INTRODUCTION

The Air Force Office of Scientific Research Technical Report Summaries are published quarterly as of March, June, September, and December of each calendar year. They consist of a brief summary of each AFOSR technical report received in the Technical Information Division and submitted to the Defense Technical Information Center (DTIC) for that quarter. The summaries contain two indexes for easily locating the technical reports that may be of interest to the user. These are followed by abstracts of the reports.

1) SUBJECT INDEX

- a. Subject Field
- b. Title of Report
- c. AD Number (Accession Number)

2) PERSONAL AUTHOR INDEX

- a. Primary Author
- b. Title of Report
- c. AD Number

AFOSR does not maintain copies of technical reports for distribution. However, you may obtain any of these reports if you are a registered government agency or government contractor with DTIC, by requesting the AD number of that report from the DTIC, Cameron Station, Alexandria, Virginia, 22314.

PURPOSE

The purpose of this report is to inform Air Force Laboratories about the science that the Air Force Office of Scientific Research is supporting.

AFOSR MISSION

The Air Force Office of Scientific Research (AFOSR) is the Single Manager of the Air Force Defense Research Sciences Program (Program Element 61102F) and the primary Air Force agency for the extramural support of fundamental scientific research. The AFOSR is organizationally under the DCS/Science and Technology, Air Force Systems Command.

AFOSR awards grants and contracts for research in areas of science relevant to the needs of the Air Force. Research is selected for support from unsolicited proposals originating from scientists investigating problems involving the search for new knowledge and the expansion of scientific principles. Selection is on the basis of scientific potential for improving Air Force operational capabilities, originality, significance to science, the qualification of the principal investigators, and the reasonableness of the proposed budget.

KEY TO READING THE DATA

The summaries consist of two indexes and the abstracts. From one of the two indexes, locate the AD number of the report that is of interest to you. Use this number to locate the abstract of the report in the abstracts section. The first report submitted to DTIC during the quarter (the one with the lowest AD number) appears on the last page of the abstracts section. The last report submitted to DTIC during the quarter (the one with the highest DTIC number) appears on the first page of the abstracts section. The following terms will give you a brief description of the elements used in each summary of this report.

DTIC Report Bibliography - DTIC's brief description of a technical report.

Search Control Number - A number assigned by DTIC at the time a bibliography is printed.

AD Number - A number assigned to each technical report when received by the DTIC.

Field & Group Numbers - (appearing after the AD number) First number is the subject field and the second number after the slash is the particular group under that subject field.

Corporate Author/Performing Organization - The organization; e.g., college/university, company, etc., at which the research is conducted.

Title - The title of the technical report.

Descriptive Note - Gives the type of report; e.g., final, interim, etc., and the period of the time of the research.

Date - Date of the technical report.

Pages - Total number of pages contained in the technical report.

Personal Author - Person or persons who wrote the report.

Contract/Grant Number - The instrument control number identifying the contracting activity and funding year under which the research is initiated.

Project Number - A number unique to a particular area of science; e.g., 2304 is the project number for mathematics.

Task Number - An alphanumeric number unique to a specific field of the main area of science; e.g., 2304 is the project number for mathematics and A3 is the task number for computational sciences.

Monitor Number - The number assigned to a particular report by the government agency monitoring the research. The number consists of the government monitor acronym, the present calendar year and the technical report assigned consecutively; e.g., AFOSR-TR-83-0001 is the first number used for the first technical report processed for Calendar Year 1983.

Supplementary Note - A variety of statements pertaining to a report. For example, if the report is a journal article, the supplementary note might give you the journal citation, which will include the name of the journal the article it appears in, and the volume number, date, and the page numbers of the journal.

Abstract - A brief summary describing the research of the report.

Descriptors - Key words describing the research.

Identifiers - Commonly used designators, such as names of equipment, names of projects or acronyms, the AFOSR project and task number, and the Air Force Research Program Element number.

CONTRACT NO. F49620-78-C-0071

PROJECT NO. 2307

TASK NO. A2

MONITOR: AFOSR
TR-84-0130

UNCLASSIFIED REPORT

ABSTRACT: (U) Experimental studies examined the breakdown of initially laminar vortex rings during impact with both solid and free surfaces in a quiescent environment, and with a solid surface beneath a developing laminar boundary layer. Flow interactions were visualized in water using dye and hydrogen-bubble techniques and recorded with a high-speed video system. When a vortex ring approaches a surface the resulting flow interaction appears to be chaotic and turbulent, but is actually a very organized viscous-inviscid process which rapidly disperses the vorticity of the vortex ring throughout the surrounding fluid. Described is the flow interaction which integrates the following phenomena: (1) generation of secondary vorticity of opposite sense to that of the vortex ring; (2) deviations in the trajectory of the vortex ring from that predicted by classical theory; and (3) the processes of organized dispersal of vorticity. The process by which vorticity dispersal occurs is dependent upon the initial Reynolds number (Re sub 0) of the vortex ring. For very weak rings, i.e. Re sub 0 less than 350, vorticity is dispersed by laminar diffusion. For stronger rings, vorticity dispersal occurs discretely through formation of secondary and tertiary vortex rings (SVR and TVR) via a viscous boundary layer

AD-A138 999

AD-A138 999

UNCLASSIFIED

PAGE

1

EVPO2F

AD-A138 999 CONTINUED

process. Vorticity dispersal continues as a result of Biot-Savart-type interactions of the SVR and TVR with the original or primary vortex ring. During this interaction the diameter of the SVR is compressed, causing an instability in the SVR which is characterized by an azimuthal waviness.

SUPPLEMENTARY NOTE: Pub. in Proceedings of AIAA Aerospace Sciences Meeting (21st) Reno, NV, Jan 84.

ABSTRACT: (U) The composite velocity procedure is applied to a reduced form of the Navier-Stokes equations where viscous effects are neglected only in the normal momentum equation. Subsonic and mildly transonic flows are considered for boattail and airfoil geometries. The composite formulation defines viscous and potential-like velocity components. These variables are coupled in a strongly implicit solution procedures (CSIP) and simulate a coupled interacting boundary layer-potential flow solver with a single system of equations. Complete second-order accurate solutions are obtained for laminar and turbulent flows where separation bubbles and weak shocks are present. The effects of inflow and outflow boundary conditions are examined and a procedure for reducing storage of the CSIP is presented. (Author)

TASK NO. C1

MONITOR: AFOSR
TR-84-0108

UNCLASSIFIED REPORT

ABSTRACT: (U) New materials, new means of fabrication, and new device structures for high density magnetic bubble devices are being pursued. A large portion of the research is directed at ion implanted contiguous disk devices which offer sixteen times the bit density of permalloy devices now being sold by U.S. OEM manufacturers. The effects on ion implantation on garnet are being studied with the goal of developing improved garnet materials and fabrication techniques for submicrometer bubble size devices. The behavior of charged walls which act to propagate the bubble domains in these devices is being investigated and correlated with the ion implantation, mask pattern design, and device performance. Unique work with transmission electron microscopy in ion implanted garnets has enabled us to directly observe structural changes produced by ion implantation in patterned devices. During the past year 0.5 micrometer bubbles were propagated in ion implanted contiguous disk devices. Work is being carried out on current-access perforated-sheet technology which offers four times the bit density of presently manufactured devices and order of magnitude higher data rate. During the past year bubble logic gates were demonstrated in this technology. Finally a current-access ion-implanted device structure which offers the high density of field-access contiguous-disk technology and the high performance of current-access technology is being pursued.

UNCLASSIFIED REPORT

ABSTRACT: (U) The transmission of digital imagery has become a necessity in recent times. Systems such as communications and weather satellites, facsimile, remote control, and machine intelligence can and do make use of data compression techniques to reduce bandwidth and power consumption. Research on these techniques has led to one form of image data compression which achieves good image quality for intraframe coding at low data rates. This technique is known as Adaptive Stochastic Picture Coding (ASPC) which consists of a one-dimensional unitary transform for column-wise decorrelation used in conjunction with Adaptive Differential Predictive Coding Modulation (ADPCM) for the row-wise decorrelation, followed by quantization to give the desired data compression. This system requires use of quantization techniques which limit system performance. Optimization of adaptive scalar quantizers and use of vector quantizers aid in the adaptation of the system to variations in the image statistics. This report represents a study of such quantizers in the ASPC system. By examining these quantization methods, it will be shown that it is vital that the proper quantizer be incorporated into the system to achieve a particular data rate at desired distortion levels. ABSTRACT: (U) The research undertaken under the AFOSR Grant included three related projects: the production and characterization of a dense plasma target for a Relativistic Electron Beam (REB)-Plasma and REB-Neutral Gas heating experiment, the development of plasma diagnostics for REB-Plasma and REB-Neutral Gas heating experiments, and finally, the development of soft x-ray diagnostic techniques of imploding liner experiments. This report has three principal sections. Section II, Characterization of a Dense Plasma Source, summarizes the results of the plasma gun research activities undertaken. That work was in the plasma target production and characterization area for planned REB-Plasma heating experiments. Section III, Intense REB-Neutral Gas Heating experiments, details the result of diagnostic development for experiments performed in this area. Section IV, Space and Time Resolved Spectroscopy of High Energy Density Aluminum Plasmas, presents results of such measurements made on the plasma produced by the SHIVA imploding foil experiment.

ABSTRACT: (U) The overall objective of the project was to design economical and informative testing of subacute and chronic toxicity of new volatile substances. The specific objectives were: (1) to prepare a mathematical model for simulation of uptake, distribution, and elimination of vapors with capacity-limited clearance; (2) to obtain experimental data supporting the model; (3) to study the factors affecting nonlinearity of clearance (concentration dependence, interference of inhalation of other vapors). The main accomplishments are: (1) A program for mathematical solution of a multi-compartmental model for simulation of uptake, distribution, and elimination of vapors having a capacity limited elimination pathway was prepared for the Apple II plus computer and tested by simulating a variety of trichloroethylene and halothane exposures. (2) Three methods for determination of metabolic clearance were tested: (a) systemic clearance was determined from the concentration differences in inhaled air and arterial blood; (b) intrinsic clearance in organs was determined from distribution of inhaled chemicals in the body during steady state; (c) intrinsic clearance by each metabolic pathway was determined from distribution and elimination of metabolites. (3) The retention of vapors of water soluble chemicals in trachea was determined and the significance of retention of chemicals in respiratory

ABSTRACT: (U) Optical data processing has not yet achieved its potential of increased capacity and speed compared with conventional electronic techniques, primarily for lack of a practical real-time image modulator, and because optical techniques have been almost exclusively limited to linear operations. The continuing research outlined in this report attacks these issues by studying the implementation of real-time nonlinear parallel-processing techniques. The various implementations studied in this program all employed real-time liquid-crystal light valves developed and specially modified for these tasks.

ABSTRACT: (U) Laser induced bunch lengthening has been measured on the ACO Storage Ring Free Electron Laser (SRFEL) in the anomalous bunch lengthening regime. The experimental results show correlations between the appearance of coherent modes in the electron bunch and anomalous behavior in the presence of the laser. Simultaneous time resolved laser induced bunch lengthening, mode strength, bunch length, and synchrotron sideband measurements were made as anomalous thresholds were traversed several times by changing the ring laser accelerating voltage. Bunch shortening, multiple time constants, and oscillatory behavior are among the phenomena which have been observed. (Author)

ABSTRACT: (U) Conjoint measurement theory is examined through a prototype example in which a fighter aircraft is subjectively rated on two factors. As a first step, a multifactor ordinal scale is developed. This ordinal scale provides a meaningful measure of aircraft quality. Interval scales of aircraft quality are produced by the basic analysis of variance model and two conjoint measurement methods: delta scaling and the computer algorithm MONANOVA. These methods produce interval scales that differ by constant factors, as guaranteed by the theorem for additive conjoint measurement. The interval scale does not appear to be an improvement over the ordinal scale in the prototype example. There is no assurance that a specific conjoint measurement model can be used to improve the data. Major changes in the interval scales are caused by small perturbations in the rating matrix. ABSTRACT: (U) In the second year of the AFOSR grant to examine the sublethal effects of water soluble fraction (WSE) of JP-4 jet fuel we have completed most of the work on the petroleum derived JP-4. Fractionators have been built and used to generate constant concentrations of the WSE JP-4 that were used to determine the lethal and sublethal effects on bluegill sunfish (*Lepomis macrochirus*) and selected aquatic invertebrates. The dynamic 96 hour LC50 for the WSE JP-4 for the bluegill was determined to be 26.2%. (This is percent of the maximum soluble amount of JP-4.) The concentration of the WSE JP-4 which causes a detectable shift in the ventilatory functions (rate and amplitude) was determined to be 5.1% WSE. In the second year of research producing cultures of aquatic invertebrates were established, flow-through test systems were designed and constructed, and toxicity tests with the water soluble fraction (WSE) of petroleum JP-4 were begun with 3 invertebrates, the oligochaete, *Aelosoma headleyi*, a benthic collector gatherer; the cladoceran *Daphnia pulex*, a planktonic filter-feeding crustacean; and, the dipteran *Paratanytarsus parthogenica* (Freeman) (= *Tanytarsus dissimilis* Joh.), a substrate associated collector gatherer.

ABSTRACT: (U) This paper presents an experimental investigation comparing the mass and energy content of fully formed laminar vortex rings in air with that of the original pulse which generated them for a variety of initial and boundary conditions. In particular, the fractional entrainment of mass and the partition of initial energy between kinetic energy of translation and kinetic energy of rotation is studied. It is found that a large degree of control can be exercised for the determination of the vortex energetics, as well as its final configuration. A technique is presented which enables calculation of kinetic energy of rotation from movie sequences. The ratio of characteristic translational speed to characteristic rotational speed is shown to be a useful parameter for correlation of data. Data on vortex size and speed are presented using this correlation and it is seen that all data, regardless of initial and boundary conditions, fall on a single curve. A theoretical curve is derived and it is seen that the data compare well with it. (Author)

ABSTRACT: (U) Local film cooling effectiveness on a gas turbine blade with a row of discrete cooling jets was measured using a mass transfer technique. Emphasis is placed on phenomena near the end wall of the blade. This region contains a horseshoe vortex system modified by a passage vortex. On the concave (pressure) surface the film cooling performance is not greatly altered by the presence of the end wall. On the convex surface of the blade the film cooling is essentially absent in a triangular region extending from near the region of peak curvature on the blade to its trailing edge. This unprotected region closely corresponds to location of the passage vortex as indicated by flow visualization. The passage vortex sweeps away the injected coolant flow from the surface. Upstream of the unprotected area the injected flow is skewed toward the middle span of the blade. End wall influence extends about one-half cord length up from the end wall in the present experiments.

ABSTRACT: (U) This study endeavors to elucidate the acute mechanisms adapted by the body to reduce cholinergic in order to fend off the toxic effects of anticholinesterase poisons. The effect of DDVP on rat brain acetylcholine content was characterized. The drug increased ACh in hemispheric structures (striatum, hippocampus, cortex) but not in cerebellum or midbrain-hindbrain. Pretreatments with atropine or reserpine only partially prevented the DDVP-induced increases. These and other experiments suggest that DDVP acted through a feedback mechanism secondarily to muscarinic receptor stimulation by the protected synaptic ACh. The feedback activation mediated by a monoamine leads to intraneuronal storage of ACh. Another fraction, perhaps smaller, accumulates extraneuronally and likely is responsible for the toxicity.

ABSTRACT: (U) Ground-based magnetometer data, recorded at AT&T Bell Laboratories' stations located at low to mid-latitudes (L=2-4) and AFGL station (L=2-3), have been analyzed to search for associations between daytime Pc3-5 pulsations (15-240 second periods) and solar wind parameters measured by instrumentation on board the IMPJ spacecraft. The statistical analysis techniques used in the work (power spectral analysis, correlation analysis, multiple linear regression methods) have led to the discovery and quantification of relationships between hydromagnetic waves in the magnetosphere as manifested by magnetic pulsations and interplanetary parameters. Multiple linear regression (MLR) analyses showed that the most important interplanetary parameter controlling ground hourly magnetic energy (in the period range 60-240 seconds) was the solar wind speed. MLR analyses further showed that hourly magnetic energy in the 15-60 second period range was also controlled by the solar wind speed but more so by the interplanetary magnetic field direction.

ABSTRACT: (U) The fluid motion about an elliptic cylinder impulsively set into translational and rotational motion is obtained by the method of matched asymptotic expansions for small time and large Reynolds number. The constraint of the perturbation model is that the boundary layer thickness and the distance of travel are of the same asymptotic order. It is found that pitch-up motion or rotation accompanying translation at an angle of attack is indeed capable of preventing the early formation of a leading edge separation bubble. Even before evident in the streamline pattern, the incipient separation bubble is accompanied by a characteristic vorticity signature in the vicinity of the leading edge that is quite different from that with rotation. Further, the onset of an adverse pressure gradient is displaced rearward from its location for pure translation. The pre-Kutta condition lift evidently arises with the local acceleration that is a consequence of the displacement effect of the growing boundary layer. (Author)

ABSTRACT: (U) The focus of the research effort is the
understanding of three-dimensional shock wave-turbulent
boundary layer interactions. The approach uses the full
mean compressible Navier-Stokes equations with turbulence
incorporated through the algebraic turbulent eddy
viscosity model of Baldwin and Lomax. During the present
year of the research effort, the three-dimensional shock
boundary layer interaction generated by a 10 deg sharp
fin has been computed at Mach 3 for a Reynolds number
280000. These results, together with previous
computations of the same configuration at Reynolds number
= 930000, are compared with experimental data for pitot
pressure and yaw angle. The agreement with the
experimental data is good, and the theory accurately
predicts the recovery of the boundary layer downstream of
the interaction of Reynolds number = 280000. The computed
flowfield is employed to analyze the structure of the 3-D
interaction through contour plots of flow variables. Also,
during the present year, the investigation of the 2-D
turbulent supersonic compression corner at Mach 3 was
completed. The relaxation modification to the Baldwin-
Lomax model was found to yield reasonably accurate

UNCLASSIFIED REPORT

ABSTRACT: (U) This document describes progress toward development of a general capability for high resolution microwave surveillance and imaging using large, sparse, self-cohering arrays. During the last five years progress has been made in the following areas: understanding of the unique advantages of large, self-cohering arrays; development of advances system concepts, including the air-borne radio camera; enhanced self-cohering capability and experimental demonstration of that capability; and development of techniques for improving microwave image quality, including handling of the high sidelobes associated with very sparse arrays. A number of other practical issues associated with large self-cohering arrays have also been examined.

DESCRIPTORS: (U) *Radar antennas, *Search radar, *Sidelobes, *Radar receivers, Antenna apertures, Microwave equipment, Test and evaluation, Radio equipment, Sparse matrix, High resolution, Test methods, L band, Microwaves, Augmentation, Images, Spaceborne, Arrays, Surveillance, Quality, Airborne

UNCLASSIFIED REPORT

ABSTRACT: (U) It is hypothesized that transfer RNAs mediate endogenous promotion of carcinogenesis subsequent to chemical carcinogen initiation, and that without the appropriate changes in tRNA metabolism, the ultimate expression of the neoplastic state will not be attained. Current studies are concentrating on tRNA ribosyltransferase modification reactions which are considered to be the pivotal molecular aberrations in this process. A normal human cell culture model system responsive to phorbol ester tumor promoters was developed which allows the evaluation of the role of tRNA in promotion of carcinogenesis. Chronic exposure to the tumor promoters induces a transient 5 to 10-fold increase in the saturation density of human cells if the treatment is initiated at early population doublings in culture in medium supplemented with elevated levels of specific amino acids. A significant decrease in queuine modification in the anticodon of cellular tRNAs precedes the transient 5 to 10-fold increase saturation density, and queuine modification increases prior to the subsequent decrease in saturation density. The increase in queuine modification correlates to the induction of an endogenous queuine salvage pathway. Most importantly, the addition of excess exogenous queuine inhibits the transient increase in saturation density induced by the tumor promoters, i.e., it blocks the expression of a

ABSTR/CT: (U) Experimental work on the fatigue crack growth characteristics of high strength P/M (Powder Metallurgy) aluminum alloys has been extended, with particular attention given to crack closure in the near threshold region as a function of R. It has been conclusively shown that the R-dependence of the threshold level is directly related to closure. In the absence of closure as in ultra-fine grained material the threshold level is independent of the R-ratio. Experimental work has been initiated on the growth of fatigue cracks under variable amplitude loading conditions. An approach to deal with topics such as the anomalous growth of short cracks, the non-propagation of cracks from notches, fatigue notch sensitivity, and the notch size-effect in fatigue has been developed. A comparison of the fatigue behavior of powder metallurgy and ingot metallurgy products has been initiated. Thus far out work indicates that P/M products can be produced which are free from manufacturing defects which might degrade fatigue properties of these high strength aluminum alloys. The fatigue properties are responsive to grain size, fracture toughness, and the degree of closure developed.

ABSTRACT: (U) This report describes progress into research on the interaction of droplets with shock waves, the mixing of co-axial jets in the near region, the influence of nearby solid boundaries on multi-hole probes, and the behavior of shock trains in ramjet inlets. The study of the mixing of coaxial jets has been completed with the submission of a PhD dissertation. Appropriate software for laser velocimetry data reduction has been prepared for use with the droplet-shock wave study, and a computer program for the description of droplet shock wave interaction has been generated. Preliminary measurements of solid boundary influence on five-hole probe readings have been taken, and optical data for shock trains in ramjet inlets have been obtained from both a water analogy rig and a supersonic wind tunnel.

UNCLASSIFIED REPORT

ABSTRACT: (U) Methods for selecting features of evoked patented (EP) waveforms to improve classification accuracy are described. It is found that use of an exhaustive search procedure gives moderate improvement over forward sequential feature selection and stepwise linear discriminant analysis procedures. A new procedure for classification using a combination of temporal and spectral representations of the data is described. Experimental results are presented illustrating the effectiveness of time-varying filters for processing EP waveforms. It is shown by means of computer simulations that much greater noise reduction is obtained with time-varying filters than is possible by any of the more conventional procedures that utilize time-invariant filters. At the same time the underlying waveforms are preserved by the filtering process. Modifications of a computer controlled display system to give precise timing measurements are described. Data showing the reduction in latency variance of EP components are presented. Reductions in the standard deviations of about 20% were obtained. Experimental measurements of EP waveforms using a Sternberg paradigm are described. Preliminary analysis of the results shows an apparent substructure in the P300 and a significant correlation of certain of the P300 components and reaction time. (Author)

SUPPLEMENTARY NOTE: Presented at the Computational Techniques Conference, 28-31 Aug 83, Sydney (New South Wales).

ABSTRACT (U) The evolution of numerical techniques for solving problems in Fluid Dynamics is followed, in outline, from the days when Digital Computers were first available, at the end of the Second World War, to the present time, when the Computer Aerodynamic Simulator is being assembled. In this period the range of numerical methods has been broadened five fold, while the speed and capacity of computers have increased by several orders of magnitude. Two areas close to the author's interests are selected to illustrate these changes. The first concerns the extension of the Method of Integral Relations to apply to laminar and turbulent boundary layer problems, including internal flows, separated flows and turbulent mixing flows. The second area deals with unsteady inviscid compressible flow in one or more dimensions and a discussion is given of the relative merits of Godunov and Glimm techniques. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This research effort studied the effects of hydrazines and organophosphates on various synaptic processes. The cyclic nucleotide related portions of this study included an examination of the effects of hydrazines upon synaptic membrane adenylyate cyclase, cyclic nucleotides and any dynamic membrane events which might be related to the above processes. We were able to show distinct effects of hydrazines upon both catalytic moiety and catalytic moiety-G unit regulated adenylyate cyclase. The calcium calmodulin kinase studies in this project investigated the effects of hydrazines and organophosphates on isolated membrane fractions and intact synaptosome preparations. We found that hydrazines and organophosphates have effects on the incorporation of 32 p-phosphate into several specific synaptic proteins and attempted to probe the molecular mechanism mediating the effects of these compounds. These studies provide an insight into the toxic effects of hydrazines and organophosphates on neuronal tissue and may help develop effective methods to prevent and treat these effects in man.

UNCLASSIFIED REPORT

ABSTRACT: (U) An almost linear optimization problem of importance in vibration isolation has been identified and algorithms were developed to minimize the forced vibrational response of structural systems. The constraints can be either displacements of accelerations. These algorithms have been studied for transient response, frequency response and stationary random using the direct dynamic solution. Multiple response points and loading conditions may be used. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The original objective of this project was, first, to study the effect of adsorbed ions on the electrosorption of organic molecules and vice versa and, secondly, to study the kinetics of formation of condensed films. The first objective was achieved, although the results obtained were rather unexpected; the second objective was met far beyond our original hope, as it proved possible to develop an entirely new approach to the general problem of nucleation and growth. This work is continuing.

ABSTRACT: (U) The size and cost of manufacturing equipment has made it extremely difficult to perform realistic modeling and simulation of the manufacturing process in university research laboratories. Likewise the size and cost factors, coupled with many uncontrolled variables of the production situation has even made it difficult to perform adequate manufacturing research in the industrial setting. Only the largest companies can afford manufacturing research laboratories; research results are often held proprietary and seldom find their way into the university classroom to aid in education and training of new manufacturing engineers. It is the purpose for this research to continue the development of miniature prototype equipment suitable for use in an integrated CAD/CAM Laboratory. The equipment being developed is capable of actually performing production operations (e.g. drilling, milling turning, punching, etc.) on metallic and non-metallic workpieces. The integrated CAD/CAM Mini-Lab is integrating high resolution, computer graphics, parametric design, parametric N/C parts programmings, CNC machine control, automated storage and retrieval, with robotics materials handling. The availability of miniature CAD/CAM laboratory equipment will provide the basis for intensive laboratory research on manufacturing information systems.

UNCLASSIFIED REPORT

ABSTRACT: (U) An apparatus and methodology for a high speed kinetic assay of purine efflux has been developed. The procedure is based on a flow system with a membrane filter to remove preloaded L5178Y cells and a sensitive rapid detector of the fluorescence emission of a buffer that contains a transport substrate, 2-aminopurine (AP). Two other purines interact rapidly with the AP carrier, hypoxanthine and uric acid. The rate of AP efflux from preloaded cells is increased by hypoxanthine in the external buffer and the efflux rate is decreased by uric acid in the buffer. Perfluorodecanoic acid (PFDA), adenine, or xanthine in the external buffer have no direct effect on the rate of AP efflux. In comparison with the controls, L5178Y cells were given a prior incubation with 200 microgram/ml PFDA at 30 C for 24 hr. These cells were preloaded with 100 micromolar AP and the excess substrate was removed by rinsing the cells with cold buffer. The prior incubation of the cells with PFDA produces a total inhibition of the efflux of AP. On the other hand, a prior incubation of the cells with PFDA plus 50 micromolar/ml bovine insulin produces approximately 40% inhibition in comparison with controls. These findings suggest that purine carrier exists in an active and an inactive form; PFDA treatment inhibits formation of active carrier. Insulin appears to stabilize

UNCLASSIFIED REPORT

ABSTRACT: (U) The main objective of this research project is to study the low energy electron precipitation and auroral phenomena over polar regions. The research is based on using various types of measurements from several USAF satellites at both low altitude polar orbits and high altitude geosynchronous orbits. These are focused on: (1) to investigate the different kinds of polar electron precipitations such as various auroral displays, the polar cusp region, conjugate photoelectrons, polar rain over the polar cap; (2) to determine precipitation characteristics for various kinds of magnetospheric and geophysical phenomena; (3) to investigate the physics and configuration of the polar cusp region and the polar cap region; and (4) to understand the morphology of magnetospheric particle population. The results of these studies can lead us to a better understanding of the interaction between the solar-wind and the geomagnetic field and also the coupling between the magnetosphere and the ionosphere.

ABSTRACT: (U) A multi-sweep relaxation procedure is applied for inviscid and parabolized (pressure-elliptic) Navier-Stokes (PNS) equations. Boattail, finite flat plate and NASA X012 airfoil geometries are considered for incompressible and subsonic inviscid, laminar and turbulent flow. The equations are written in a conformal body-fitted coordinate frame and differenced on a staggered grid in order to give second-order accuracy for the inviscid flow and somewhere between first and second-order accuracy for the PNS solutions. A full second-order scheme is also discussed. Separation, trailing edge and stagnation point flow are evaluated. The effects of normal pressure gradients for laminar and turbulent flows are compared. A multi-grid procedure is applied in order to speed convergence rates for fine meshes and/or large computational domains. (Author)

ABSTRACT: (U) Metal, dielectric and semiconductor films have been deposited by laser chemical vapor deposition (LCVD) using both pulsed and cw laser sources on a variety of substrates. For LCVD on substrates such as quartz, the deposition was monitored optically in both transmission and reflection using a collinear visible laser and the depositing CO₂ laser. Deposition initiation and rate were correlated with irradiation conditions, the laser generated surface temperature, and the changing optical properties of the film/substrate during deposition. Single crystallites of W greater than 100 micrometers tall were deposited using a Kr laser on Si substrates. (Author)

ABSTRACT: (U) Three concepts are used to illustrate how a small number of simple mechanisms can generate a wide diversity of complex biological phenomena, as well as parametric experimental tests of the models that simulate these phenomena. One is the classical concept that a membrane equation can model fast electrical responses in cells. The second is the concept that mass action processes can be coupled to the membrane equation as conductance terms. The third is the concept that gating processes can be used to model the mass action dynamics of chemical transmitters.

ABSTRACT: (U) A plane wave emergent from a scattering layer is modeled as a boundary value problem. The wave is specified at $z = 0(+)$ by a unit amplitude and a phase prescribed by a homogeneous isotropic random function with a power law spectrum and Gaussian statistics. It is shown that the statistics of the wave propagating in free space away from the boundary cannot be Gaussian, except perhaps in the far field region where the scattering is saturated. It is also shown that the amplitude and intensity spectra of this wave each satisfy specific scaling relations. Such a wave has been called a diffractal by Berry and herein this paper further develops some of his ideas on diffractals, in particular extending his discussion from two or three spatial dimensions. A study of the 'cintillation index indicates that a diffractal is not an unreasonable model of a radio wave passing through the ionosphere, as it does in satellite communication. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This program covers the growth and assessment of Gallium Arsenide, and related compounds and alloys, for use in microwave, millimeter, and optical devices. It also covers the processing of the material into devices, and the testing of the devices. Both molecular beam epitaxy (MBE) and organo-metallic vapor phase epitaxy (OMVPE) are used for growth. Modulation doped heterostructures and very short gate field effect transistors are two areas covered.

ABSTRACT: (U) The authors derive the most general equations of motion for the electrons and the electromagnetic field including the effects of diffraction and pulse propagation. The field evolution is expressed in terms of the amplitudes and phases of a complete set of transverse modes. The analytic solution is given in the small signal regime, where the theory is shown to be in excellent agreement with a recent experiment. (Author)

ABSTRACT: (U) This research program has been concerned with evaluating the influence of various stressors, physiological and psychological, on man and subsequently determining the capacity of the individual to successfully adapt to these environmental influences. In the process of these investigations some 42 peer-reviewed manuscripts were published. They have dealt with the responses to exercise, cold and hot environments, hypoxia, toxicological substances, sleep and psychological stresses. The subjects for these studies have included both sexes. In general while some facets of man's adaptability have been resolved, it is clear that numerous problems remain to be investigated.

ABSTRACT: (U) The materials assembled in this report represent work conducted with AFOSR support at the Cognitive Psychophysiology Laboratory during the reporting period. Appendix A of the report contains abstracts and papers that have been presented at various scientific meetings. In the text we present a brief review of these studies. For studies not included in Appendix A, a longer review is given. Appendix B gives a list of items that are either final versions of materials that were presented in previous progress reports or review chapters.

ABSTRACT: (U) Professor Shunro Watanabe of Japan has been visiting our group since March, 1982. In the past year he has been able, with the support of our group, to develop a major new program for solving in closed form a wide variety of ordinary differential equations. The MACSYMA system uses two large packages for solving ODES. Professor Watanabe's approach is to convert most second order ODES into instances of the so-called P-function. These functions, originally due to Riemann, have been extensively studied by the Japanese mathematician Fukuhara (also spelled Hukuhara). For the past year, Watanabe has implemented a package that transforms a large class of equations into P-functions. He has used Kamke's table as a test bed. Several examples from Kamke using this package, are given in Appendix I.

UNCLASSIFIED REPORT

ABSTRACT: (U) The results of the first year of an experimental investigation of the abnormally high turbulence level and mixing layer growth rate characteristics found in the upwash regions of V/STOL flows in ground effect are presented. The overall objectives of this program were to examine the origin of the increased fluctuations, to systematically characterize the development and structure of the upwash, and to determine the parameters that influence these characteristics. The approach adopted was to investigate the fundamental turbulent V/STOL upwash mechanisms in increasingly more complex flow configurations. In the first year's effort, a two-dimensional upwash was formed by the collision of opposed two-dimensional wall jets. Extensive measurements were made in the two-dimensional wall jet to establish the starting conditions of the upwash. Evaluation of these measurements have shown classical wall jet behavior, and by the time the wall jet reaches the collision zone, both the mean and turbulence profiles are fully developed. A unique set of velocity profiles was obtained at six locations in the upwash. By using an X-probe anemometer, two components of the velocity were found simultaneously. This baseline set of two component velocity profiles has never been reported

AD-A137 775

AD-A137 775

before. While the turbulence levels and mixing layer growth rates were larger than those found in a free two-dimensional jet, these values were less than those reported by previous investigators.

ABSTRACT: (U) The three major research areas have been parallel structuring of computations, basic software for support of parallel computations and parallel architectures and supporting hardware. The work on parallel structuring of computations falls into three categories. First of these is parallel structuring of complete programs or applications. The example to be discussed below is a Monte Carlo simulation of particle movement. The second category is parallel formulation of specific numerical algorithms. The third topic is parallel formulations of non-numeric algorithms, in particular radix sorting. Design, development and analysis of basic software for parallel computing has received major emphasis. Basic software for support of parallel computations on reconfigurable network architectures is an almost entirely unstudied problem area. The third major area is continuing development of parallel architectures and hardware support for parallel architectures in the context of the Texas Reconfigurable Array Computer.

ABSTRACT: (U) The aspect of Robustness for linear
multivariable systems is analyzed in time domain. Both
Stability Robustness and Performance Robustness are
combinedly considered to meet stability and performance
requirements. First a stability robustness condition in
time domain (in terms of eigenvalues) is presented and
examples are given which indicate that the proposed
robustness condition is less conservative than the
corresponding frequency domain condition as well as
another recently proposed time domain condition, both
given in terms of singular values. Next a technique is
presented to further reduce the conservatism of the
proposed condition. A design algorithm that incorporates
both stability robustness and performance robustness into
the design procedure suggested in the summer faculty
program report, is modified with the help of new
definitions of robustness indices. Computer software to
implement the algorithm is presented along with simple
examples to illustrate the concepts. Based on the
experience gained by the minigrant research, areas of
future research are recommended. (Author)DESCRIPTORS: (U) *Algorithms, *Control systems, *Time
domain, Control theory, Computer programs, Closed loop

ABSTRACT: (U) During the past year microwave and millimeter wave emission experiments on three systems were carried out. System one is a Rippled-Field Magnetron and represents a hybrid between a conventional magnetron and a free electron laser. System two is a Circular Free Electron Laser in which a rotating ring of relativistic electrons is subjected to an azimuthally periodic magnetic field. The third system concerns an inverted Relativistic Magnetron.

UNCLASSIFIED REPORT

ABSTRACT: (U) The products of the very rapid reactions of electronically-excited Ar, Kr and Xe atoms with several oxygen-, hydrogen- and halogen-containing compounds have been investigated using the saturation ion-current technique and emission and atomic resonance fluorescence spectroscopy in discharge-flow systems. New insight has been obtained into the mechanisms of the channels leading to chemiionization and noble-gas halide formation. Energy transfer leading to molecular dissociation is the major and often the dominant channel, with one or more atoms being eliminated in strong preference to elimination of molecular or electronically-excited fragments. For the excited noble gas atoms, the high quenching efficiency and dominance of dissociation and ionization channels are associated with the availability of accessible acceptor states of the quenching molecule, as revealed by its absorption spectrum. It is proposed that these efficient reactions occur by energy transfer at relatively long range with no major prior distortion of the quenching molecule. It is expected that this model should be directly applicable to the reactions of certain other excited species, which exhibit a similar correlation of quenching rate constants with the availability of acceptor states at the

SUPPLEMENTARY NOTE: Presented at Proceedings of the Aerospace Sciences Meeting (21st), 10-13 Jan 83, Reno, NV.

ABSTRACT: (U) A series of measurements has been made of the velocities in the near wake of an airfoil in an unsteady flow generated by rotating an elliptic cylinder near the trailing edge. Ensemble averages of the tangential and normal velocity components and of 3 Reynolds stresses were determined for reduced frequencies based on semichord up to 8.4, angles of attack of 0 and 10 degrees. Reynolds numbers of 700,000 and 1,450,000, and chordwise positions $1.025 \times/c$ 1.2. In this region, the airfoil wake is distinct from the wake of the elliptic cylinder. The mean and unsteady velocities and Reynolds stresses diffuse rapidly so that the distinction between the contributions due to the two boundary layers on the airfoil surfaces, apparent at $x/c=1.025$, has largely disappeared by $x/c=1.20$. (Author)

ABSTRACT: (U) Earlier workers reported that the viscosity of gases can be changed appreciably by radioactive irradiation, offering a possible means of achieving drag reduction in flight. A precision skin friction drag balance and torsion disc viscometer were developed to investigate this effect. It is shown that, with practical radiation levels, irradiation has a negligibly small effect on viscosity and skin friction drag (both laminar and turbulent). This agrees with theoretical estimates of the change in viscosity due to ionisation. It has also been reported that turbulent gas flows align polar or polarisable molecules whose motion then gives rise to detectable electromagnetic radiation. A study was made of this phenomenon with a view to applications in monitoring the structure of turbulent gas flows during drag reduction experiments. It is concluded that the previous interpretation was erroneous and that the probes used were responding to vibration rather than to electromagnetic radiation. Calculations suggests that any electromagnetic signal will be at least 120 dB below the background noise level. The equipment and electronics developed in the course of the research can be used for accurate, relative measurements of skin friction drag and viscosity. The operation of the viscometer is particularly simple, with the logarithmic decrement being

UNCLASSIFIED REPORT

ABSTRACT: (U) The intent of the research was to explore, using modified algal bioassays, the possibility that algal communities in natural situations may be affected to a greater extent than would be predicted by the short residence time of toluene in water and by the bioassays that have been conducted to date. Algal cells killed or inactivated by toluene do not return nutrients to the medium. In lakes, these cells may sink out of the upper waters, removing the nutrients necessary for community recovery. Recovery may be a function of the rate of nutrient re-supply rather than of the rate of hydrocarbon volatilization. The degree of nutrient limitation and indeed the limiting nutrient involved may modify the response of the community to toluene. A nutrient-limited community may be more affected by toluene than a non-nutrient-limited one. In a nitrogen-limited community, algal growth may be stimulated. Differential toxicity may affect the outcome of species competition for nutrients. The species that is least susceptible to toluene may obtain a numerical advantage, at least temporarily, while the other species are inhibited. The duration of this advantage may depend on the rate to which nutrients are returned into the medium.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Prepared in cooperation with Illinois Univ. at Chicago Circle. Dept. of Mathematics, Statistics and Computer Science under Grant AFOSR-80-0170.

ABSTRACT: (U) The in vivo and in vitro heart rates of rats treated with 75 mg/kg PFDA was significantly lower than the in vivo and in vitro heart rates of pair-fed controls 6 to 8 days following treatment. In addition, the rate response of isolated hearts sympathetic nerve stimulation was greater in the PFDA hearts. Beta receptor binding assays were done on homogenates of hearts from PFDA and pair-fed controls 8 days following a single 75 mg/kg dose of PFDA. PFDA treatment resulted in a significant decrease in the number of cardiac beta receptors. Radioimmunoassays of serum levels of T3 and T4 indicate that PFDA produced a significant fall in the level of both of these thyroid hormones. It is concluded that PFDA produces an alteration of the normal function of cardiac membranes. This effect may be either direct or indirect via changes in thyroid hormonal levels.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report summarizes a five-year
research program on the subject of quality evaluation of
digitally derived imagery. High-resolution aerial
photography was used to create digitized images with
unclassified content comparable to that employed in
military photointerpretation operations. The digitized
imagery was used in several hard-copy and soft-copy
interpretation experiments to assess the effects of image
blur and image noise on both perceived image quality and
the ability to extract information from the images. The
soft-copy experiments included both nonprocessed and
processed imagery. Finally, quality metrics of image
quality were obtained for both hard-copy and soft-copy
images and related directly to both information
extraction performance and subjective quality scaling.

ABSTRACT: (U) For this study the application of
Artificial Intelligence methods in synthetic aperture
radars (SAR) is investigated. It was found that the
neuron-like ASE-ACE adaptive algorithm developed by
Bartis, operating in the extremizing mode suggested by
Klopf, can be used in a wide class of engineering
problems requiring that some performance function be
minimized. One such suggested application is to correct
for quadratic phase errors in SAR signal processing.

UNCLASSIFIED REPORT

ABSTRACT: (U) The original scientific objective of this basic research program was the understanding of the synthesis and chemical reactivity of organic compounds consisting of a carbon backbone containing several bis(dialkylamino) phosphine substituents, (R2N2)P. This class of organophosphorus compounds, which has received very little attention, is of potential importance as intermediates in the manufacture of materials of possible value to the Air Force in diverse applications including antioxidants, lubricity agents, elastomers, flame retardants, and fuel cell catalysts. The development of methods for the synthesis of organic compounds bearing several (R2N2)P substituents requires the availability of important dialkylaminophosphorus building blocks. In this connection major effects of the size of the dialkylamino group on the resulting dialkylaminophosphorus chemistry were documented for the first time.

ABSTRACT: (U) The continuing development of higher order programming languages has not yielded major productivity improvements in the software development process. One often mentioned mechanism for achieving significant orders of improvement are application generators, such as RAMIS, NOMAD, and FOCUS. These systems have been applied to data intensive business applications with phenomenal success. The purpose of this paper is to present the basic components of application generators and show why they yield such large productivity increases in the edp environment. The authors investigate the meaning of nonprocedural programming and show how it exists in current application generators. Then they analyze the possibility of extending application generators so that they may be used for non-edp type applications. (Author)

ABSTRACT: (U) The largest and highest quality single crystals of the tungsten bronze family ferroelectric compositions of the strontium - barium niobate family reported to date were prepared by Czocharalski growth techniques. Low frequency dielectric properties show low loss and high permittivity as expected. Accurate high frequency dielectric measurements for several compositions were made in a waveguide geometry from 30 to 100 GHz and the electric field sensitivity of the microwave refractive index, dn/dE , was evaluated by a modulation technique in the same waveguide geometry. Although high values of dn/dE were observed, an unexpectedly high dielectric loss, which does not fit accepted models for dielectric properties, was observed. This fact, coupled with a high sample-to-sample variability, suggests a commonly occurring extrinsic factor such as growth defects or sample impurities as the key element limiting the use of these materials for phase control applications in millimeter wave radar systems. Similar dielectric measurements were made on a variety of ceramic ferroelectrics. In general the losses were substantially higher in these materials. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This research was initiated in June 1982. The early work began with an investigation of commercially available application generators. This was undertaken because of a belief that such systems provide a major increase in programming productivity, at least for a narrow range of 'edp' applications. The plan called for investigating systems such as RAMIS, NOMAD and FOCUS with the goal of determining what features contributed to this improvement. The investigators were successful in that they isolated what they believe to be the major features that contribute to increased programming productivity, namely an application generator's built-in interface to a database management system, its non-procedural programming language constructs, and the high-level operators for specific operations. The main activity during the previous nine months has been to see if the investigators could design these features into a general purpose programming language. They decided to use Ada as the starting point. They needed to design an extension of Ada that permits the language to interface with a database management system. They concluded that this interface should not merely be a set of remote procedure calls, but a true extension of the language. This implied that they had to extend the type facility and provide new operators, while preserving the design principles of the language. This is the logical first

ABSTRACT: (U) The work of the past year has concentrated on experimental measurements and their analyses. The response of Ytterbium (Yb) foils, oriented parallel and perpendicular to the shock front, was obtained for well defined loading and unloading. The foils were embedded in a PMMA matrix and the longitudinal stress ranged between 0.1 and 2.0 GPa. Results have provided an empirical calibration for Yb under shock wave uniaxial strain loading. An important result from these experiments is the verification of an elastic-plastic inclusion analysis. The results of the 1.9 GPa experiment suggest that under certain conditions a dynamic inclusion analysis will be necessary. Another important aspect of this year's effort was the development of an experimental method to perform low strain-rate tensile experiments on gauge foils.

ABSTRACT: (U) In this paper the authors extend Ada to facilitate the programming of data-intensive applications. The language extensions are based upon the relational data model. The system is interfaced to a relational database management system via a new Ada type relation. The language includes basic operations on relations, commonly available in database query languages, like retrieval of data, update of tuples as well as high-level operators to combine relations to form new ones. The authors show how Ada exception handling is naturally extended to allow integrity control of the relations. In addition the authors discuss language features that enable the sharing of data among several users. Concluding the paper the authors give an extensive example application to demonstrate the power of their proposed language extensions. (Author)

ABSTRACT: (U) An interpolation technique is implemented which is applicable to terrain data defined on a rectangular grid. The technique also allows for data compaction, i.e., effectively representing the given data using less space than required by the raw data. The technique involves finding bicubic polynomials which represent the terrain surface over small subgrids. These surfaces are then pieced together to form a global surface which is both continuous and smooth over the entire region. (Author)

ABSTRACT: (U) This research focused on higher order crossings of time series and their application in spectral analysis, and on the various point processes obtained from stationary processes and their relations to reliability models. The higher order crossings theorem was extended to two dimensions, and the one-dimensional version was used to determine the connection between axis crossings and the frequency content of a stationary process. Considerable progress was made in calculating the asymptotic variance-covariance matrix for the vector of higher-order crossing counts, and time series analysis of highly nonlinear and chaotic stationary processes was carried out. The report summarizes progress in these areas (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) A substantial enhancement (by orders of magnitude) of the Sagnac effect in a passive ring resonator can be attained by using a nonreciprocal feedback. This feedback is based on the nonreciprocal element controlled by the signal proportional to the difference between intensities of counterpropagating waves, and is an opto-electronic analog of nonlinear nonreciprocity proposed by us early. Under some critical conditions, this system can exhibit directional bistability and directional switching of the counterpropagating waves. (Author)

ABSTRACT: (U) The chemi-ion ion-molecule mechanism of soot formation has gained further support by detailed studies of ion profiles through sooting flames. Langmuir probes have been used to obtain absolute ion concentrations in premixed acetylene-oxygen flames over a range of equivalence ratios extending from nonsooting to sooting flames. These data have been used in a preliminary calibration of the mass spectrometer. The effect of initial temperature on the tendency of several flames to soot has been measured. For a given premixed flame the tendency to soot decreases with increasing temperature but for a series of fuels with increasing tendency to soot, the temperature at which soot occurs increases with the tendency to soot. Ion concentrations will be measured in this set of flames. Calculations of particle electronics and coagulation rates have been initiated to determine whether the large molecular ions observed in sooting flames are the cause or effect of soot formation and in preparation for quantitative modeling of soot formation. ABSTRACT: (U) Aerodynamic characteristics of separated
and attached unsteady flow about a NACA 0012 airfoil have
been measured for reduced frequency from 0 to 8.4 and
angles of attack up to 18 deg. Results from boundary
layer and near wake ensemble averaged velocity, Reynolds
stress and surface pressure distributions are presented.
The flow was determined to be locally two-dimensional
away from the separation point (if present), within + or -
1/4 span of the airfoil centerline. A convected component
of the unsteady separated pressure field was identified,
and the dependence on reduced frequency, angle of attack,
Reynolds number and form of transition is discussed. A
geometric similarity model is suggested to explain the
presence of a periodic component measured for the
ensemble averaged Reynolds stresses. Finally, studies of
the relative importance of acoustic and upwash velocity
components of the excitation are summarized. (Author)DESCRIPTORS: (U) *Unsteady flow, *Boundary layer flow,

UNCLASSIFIED REPORT

ABSTRACT: (U) In experiments directed toward development of a simple, quantitative in vivo assay for mistranslation-inducing activity of pollutants, we have established the natural level of cysteine misincorporation into the bacteriophage T7 encoded 0.3 protein. We have also shown that this level can be increased by altering the environment of the translation machinery. This can be accomplished either by growing cells in the presence of mistranslation-inducing antibiotics or by inducing mutations which cause defective ribosomal proteins into the cells being studied. The above results were obtained using purified 0.3 protein. Additional experiments directed toward the first objective have led to a second procedure for quantitating cysteine misincorporation into 0.3 protein. A radioimmune precipitation (RIP) assay was developed which used polyclonal antibodies to 0.3 protein, SDS-polyacrylamide gel electrophoresis (SDS-PAGE), and scanning densitometry. We are currently preparing monoclonal antibody to 0.3 protein to obviate the need for SDS-PAGE and scanning densitometry. Experiments directed toward the second overall objective have provided interesting preliminary results. Trypsinization of cysteine-labeled 0.3 protein analysis of fragments by SDS-PAGE have shown that new peptide fragments are produced.

ABSTRACT: (U) The purpose of this letter is to discuss our research into parallel systems software and hardware, and parallel problem solving. Under the current grant, a detailed design and partial implementation of a parallel problem solving system, PRISM (parallel inference system), based on logic was achieved. The PRISM requires that the ZMOB parallel processor be available for use. In addition, systems software and hardware have been developed. It is estimated that ZMOB will become available for use during the Fall of 1983. Hence, a full test and debugging of PRISM cannot be achieved under the current grant. At the end of the current grant we expect to have accomplished, as a minimum, all of the objectives proposed. That is, in the area of parallel problem solving, the Initial PRISM has been fully designed; individual programs have been implemented and tested in a non-parallel environment; and investigations have been made into extensions to the initial design.

UNCLASSIFIED REPORT

ABSTRACT: (U) The efforts of the Group for Computer Studies of Strategies centered on five long-term projects: (a) The Generalized Production Rules System (GPRS) is a program which can support decision-making for a variety of expert systems in need of estimates of hidden variables. Hidden variables are such that their values can be identified only at certain times, either intermittently or periodically. In contrast, open variables are readily measureable at any time. The estimation is based on stochastic, causal relations between hidden and open variables. (b) The Quasi-Optimizer System (QO) is a program which observes and measures adversaries' behavior in confrontations, infers their strategies, and constructs a descriptive theory, i. e., a model, of each. It then identifies the components of the strategies, evaluates their effectiveness and combines the most satisfactory ones into a normative theory which is an optimum strategy in the statistical sense. (c) The advice Taker/Inquirer (AT/I) is a program which can be taught strategies by a human Advisor. The Advisor provides principles and high-level examples of actions in different situations. The system applies the strategy to test, verify and optimize the strategy. (d) The Interactive Environment for Planning and Decision Making uses two graphics screens, one displaying features of the current world, the other those of an extrapolated

UNCLASSIFIED REPORT

ABSTRACT: (U) The work conducted this year followed the projections set forth in the grant proposal rather closely. On the theoretical side, the investigators have continued to explore questions of the logical status of some of the standard data structures involved in various artificial intelligence applications involving knowledge bases. The greatest attention has been focused on frames. Exploration of the axiomatization and representation of semantic nets by similar methods has been carried out. The nodes of the net are treated by methods similar to frames. Most of the attention here has focused on the work of Woods and Brachman and the KLONE formalism. The investigators have conducted a number of explorations with their existing experimental metaProlog simulator. This simulation was coded in Edinburgh Prolog and run on Syracuse University's DEC-10 computer. Progress in these areas is discussed in greater detail in this interim report. (Author)

ABSTRACT: (U) The experimental study of a 3D skewed shock wave laminar boundary layer interaction has been carried out. The test configuration was a flat/finned plate arrangement with sharp leading edge fins having 4, 6 and 8 deg incidence relative to the free stream. The flat plate laminar boundary layer had thickness between 1.1 and 2.2 mm depending on test conditions. The unit Reynolds numbers used were 1.2 million and 2.4 million. Experimental surface data represented as surface flow visualizations and pressure distributions are presented for all test conditions. All tests were carried out at a nominal free stream Mach number of 2.25 and under approximately adiabatic wall conditions. The experimental results indicate that extended separation occurs even for the smallest wedge incidence, i.e., for a pressure ratio of 1.27 and that the extent of upstream influence is much larger in this 3D interaction than in comparable 2D interactions. Preliminary theoretical investigations show that an integral method is not suited for the study of the present interaction. The new implicit corrected viscosity method for solving the compressible Navier-Stokes equations can yield convergence speeds of order unity under suitable chosen conditions. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Two approaches to finite element analysis are now widely recognized in the engineering and mathematical communities. In both approaches the domain ω is divided into simple convex subdomains (usually triangles or rectangles in two dimensions, and tetrahedra or bricks in three dimensions) and over each sub-domain the unknown (displacement field) is approximated by a (local) basis function (usually a polynomial of degree p). Basis functions are required to join continuously at boundaries of the subdomains in the case of planar or 3 dimensional elasticity, or smoothly in the case of plate bending. The difference between the two approaches lies in the manner in which convergence is achieved. The p -version of the finite element method is a new, important, computationally efficient approach to finite element analysis. It is more robust than the conventional h -version and its rate of convergence, for domains with corners and for other singularity problems, is twice that of the h -version.

UNCLASSIFIED REPORT

ABSTRACT: (U) The purpose of this research is to see how surface roughness affects the hydrodynamic stability of a supersonic laminar boundary layer. The outcome of the first year of the program had been: (1) to demonstrate the great resistance of the supersonic flow to destabilization and tripping by roughness; (2) to choose a final roughness capable of such destabilization and tripping; and (3) to complete boundary layer surveys on an axisymmetric body so roughened as a prerequisite to the stability measurements. In the present report period the geometry was changed to a planar (flat plate) one to correct deficiencies found in the axisymmetric flow which, however, uses the same roughness geometry as before. The flow field measurements on this model have been completed, as have about 30% of the final stability measurements.

UNCLASSIFIED REPORT

ABSTRACT: (U) An analysis based on a two-layer interaction model is presented for the prediction of transonic shock-wave, boundary-layer interaction with emphasis on turbulent separated flow. In this analysis finite difference techniques are used to solve the viscous layer equations, expressed in a defect form, and the stream function-vorticity representation of the inviscid flow. A global technique is used to iteratively solve these coupled sets of equations. Normal pressure gradients and imbedded shock effects are included in the analysis. Two major conclusions can be drawn from the present work: First, favorable comparisons obtained with the separated data of Koof (Mach no. ≈ 1.4) demonstrate that the present analysis is capable of accurately resolving many of the transonic shock-wave, boundary-layer interaction. Second, these results show that, for transonic shock induced separation, the effect of displacement thickness interaction dominates over that produced by imbedded shock effects and normal pressure gradients. Calculations made with a modified algebraic turbulence model demonstrate that for separated cases the computed results are more sensitive to the turbulence model than to whether or not normal pressure gradients are included.

ABSTRACT: (U) The behavior of a model of high-strength concrete consisting of nine coarse aggregate circular inclusions in a square mortar matrix is studied under biaxial compressive loads. Constitutive equations are developed following the theory of plasticity in order to describe the behavior of mortar in biaxial compression. The bond between mortar and aggregates is simulated by an interface element. A comparison of analytical and experimental results shows good agreement. (Author)

ABSTRACT: (U) Methods have been developed to obtain relaxation spectra for highly filled cloth composites by application of torsion impregnated cloth analysis (TICA) techniques. Comparison of spectra for filled and unfilled polysulfone samples suggest that polymer-filler interactions result in substantial broadening of the relaxation time distribution although there is little change in shift parameters, glass transition temperatures, or Arrhenius activation energies. In addition, TICA loss modulus measurements suggest the presence of a previously reported weak relaxational process (liquid-liquid transition) above the glass transition temperature. Dynamic mechanical measurements of polysulfone torsion bars indicate the presence of two secondary relaxations below the glass transition temperature. These include a strong gamma peak near -100 deg C and weak beta peak near 60 deg C. Annealing or slow cooling results in a suppression of the beta peak and intensifications of the high temperature side of the gamma peak which appears to correlate with a small decrease in impact strength. Preliminary quantum mechanical calculations suggest that the gamma relaxation may represent contributions from methyl group rotations and swivel motions of isopropylidene and diphenyl sulfone moieties while more energetic diphenyl ether swivels may be responsible for the beta relaxation. No effect of thermal conditioning in the region of the liquid-liquid transition has been

ABSTRACT: (U) The results of several investigations into
the fracture, longevity (fatigue), dynamics, and
aeroelasticity of composite materials are reported. The
experimental work was conducted using Hercules graphite/
epoxy prepreg in two forms: AS1/3501-6 unidirectional
tape and A370-5H/3501-6 fabric. The topics discussed
include unnotched tensile fracture, sensitivity to
notches under tensile loading, nonlinear stress-strain
behavior, compression specimen development, damage growth
under cyclic load, and the flutter and divergence of
graphite/epoxy wings. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The objective of this research is to derive a minimum cost sequence of automatic built-in-tests (BITs) which will partition modular equipment into mutually exclusive groups of modules. Following an equipment malfunction, one of these groups will be identified by the BIT diagnostic subsystem as the group which contains the faulty module. The BITs will not detect all of the possible errors in the modules, and they may also generate false alarms by calling out a group of modules which does not contain the faulty unit. Both the cost of a BIT and the probability that a BIT will pass or fail are functions of the modules which are tested. A recursive algorithm is developed which consists of a backward computational process followed by a forward computational process. The recursive algorithm generates a sequence of BITs with a minimum cost. The algorithm is applied to a four-module sample problem to produce a numerical solution. (Author)

ABSTRACT: (U) The research procured under this contract is oriented toward the understanding and development of the flexible robot based manufacturing cells or islands which will increasingly become a basic blocks for the building of modern parts production and assembly facilities. Present work spans a hierarchy of sub-systems oriented toward the development and integration of high performance manipulators into flexible manufacturing cells. These subsystems may be divided into several levels of abstraction: Level 1: The mechanical structure and low-level (small time-constant) control of high-performance manipulators; The sensor sub-systems (force, tactile, thermal, and vision); Computer architecture and languages which form the basis of robot systems and manufacturing cells; Level 2: Integration of mechanical structure, computer system and sensor to form flexible robot systems; Level 3: The integration of systems with production and assembly machines and information contained in the manufacturer's computer-aided design database; and Level 4: Integration of the factory-wide distributed database which is central to the design, production and business functions of manufacturing.

ABSTRACT: (U) The performance of two related computer algorithms for the purpose of critical potential detection has been analyzed. These algorithms employ positive ion spectra from onboard electrostatic analyzers to determine whether a critical potential has been reached or exceeded. The day to day performances have been examined and individual ion count spectra have been checked in cases of algorithm failure to see what algorithm modifications might lead to improved performance. Additionally, it has been considered whether reliable charge detection could be obtained using a rapid response Electrostatic Analyzer with many fewer energy channels than the 64 channel SC9 experiment of the P78-2 spacecraft. This has led to development of a goodness-of-fit test based on an onboard model of the distribution function profile in the absence of charging. Preliminary tests of this algorithm suggest that it may be useful as a rapid response detection algorithm on its own or as a preliminary test to screen for suspected cases of charging to be further analyzed by one of the other algorithms. ABSTRACT: (U) The Radon transform is the mathematical basis of computed tomography. The two-dimensional (2D) Radon transform consists of a series of 1D projections along a 2D function, obtained by integrating the function along lines, while the 3D Radon transform consists of 1D projections of a 3D function, obtained by integrating over planes. In both cases, the transform serves to reduce the dimensionality of a function from 2D or 3D to 1D. For signal-processing applications, this dimensionality reduction is very useful because of the availability of sophisticated processing devices, such as SAW and CCD filters, for 1D time signals. The Radon transform permits the use of these devices with 2D and 3D data sets. The operations that can be performed with the help of the Radon transform include: convolution, correlation, Fourier analysis, bandwidth compression, space-variant filtering, adaptive filtering, calculation of the Wigner distribution and ambiguity function, and calculation of moments of an image. In all of these cases, the operations can be carried out on a 2D or 3D data set by first performing a Radon transform, then doing a sequence of 1D operations, and finally performing an inverse Radon transform.

ABSTRACT: (U) A model of the near-wall behavior of turbulent boundary layers is presented. Based on an extensive series of primarily visualization experiments, which are described in overview, the model proposes a sequence of events which give rise to the bursting behavior responsible for turbulence production in the near-wall region. The model illustrates how hairpin vortex flow structures, generated during low-speed streak break down and ejection, are also responsible for the streak regeneration process, thus defining a clear cycle of turbulence generation for the near-wall region. UNCLASSIFIED REPORT

ABSTRACT: (U) An Analysis and computational procedure have been developed for predicting the flow and heat transfer which results from coolant injection through a single row of round holes oriented at an angle to a flat surface with the injection and freestream velocity vectors coplanar. This method solves the compressible Navier-Stokes equations and utilizes 'zone embedding', surface-oriented coordinates, interactive boundary conditions, and an efficient, split LBI scheme. The approach treats the near-hole flow region where the complex film cooling flow is initially established. The initial studies considered only laminar flow in order to develop the computational procedure without the added complications of turbulence modeling. Calculations were performed on a coarse mesh at a blowing rate of 0.1 for both normal injection and injection at 45 degrees through a circular hole with the computational domain extending into the coolant hole. The results obtained were qualitatively reasonable and demonstrated the capability of the procedure for treating film cooling injection flows without simplifying assumptions in the near-hole flow region. The procedure was extended to turbulent flows and a calculation was performed for an injection angle of 35 degrees with a lateral hole spacing of three

diameters. The results for this case display the expected large secondary flow development as a result of the interaction between the main stream flow and the injected fluid. Also, the temperature distribution predictions exhibit good qualitative agreement with experimental data with the quantitative discrepancies apparently due to either the turbulence model or inadequate grid resolution.

UNCLASSIFIED REPORT

ABSTRACT: (U) Coupling of surface waves in laterally inhomogeneous source regions to teleseismic propagation paths was studied. Dimensions of the cylindrical source region and its linear gradient transition zone were varied in order to determine their effect on generation of teleseismic Rayleigh waves. By comparing amplitudes from a source region with sharp boundaries at the sides and bottom with those from a region bounded by various combinations of sharp and transition boundaries, it was determined that, for these source dimensions at the periods of interest, the more the body wave energy that leaves the source region as downgoing waves, the larger the fundamental mode Rayleigh wave. A review on the theory and application of synthetic seismograms was conducted. Emphasis was on body phase wave forms at teleseismic, regional, and local epicentral distances. At teleseismic distances, it was shown that long period body phases from shallow earthquakes are coherent at neighboring stations and that the observed waveform could be decomposed in a manner that allows determination of faulting parameters. By modeling both long and short period body waveforms using distributed point sources it is found that most earthquakes are indeed complex and that high frequency strong motions appear to be more strongly controlled by the jumps in the source time history than by the overall duration.

ABSTRACT: (U) The Space Astronomy Laboratory plans to fly an advanced gamma-ray spectrometer aboard a future Shuttle flight. The 'GRAD' spectrometer employs a new bismuth germanate (BGO) anticompton shield and n-type high purity germanium detector. BGO, because of its high atomic number, requires only 1/12 the volume and 1/6 the weight of an equally sensitive sodium iodide crystal. The n-type germanium detector is at least 25 times more resistant to neutron radiation damage than a conventional detector and has a very broad spectral response of 5 keV to 10 MeV. Neither of these materials has been subjected to the space environment as working components of a detector system. The radioactivation of the new detector materials by cosmic rays and fast neutrons, as well as other effects of launching, landing and operation in the space environment on the detector system will be monitored and calibrated. Early information on gamma-ray background from activation of the shuttle itself will also be obtained. In addition to the technological information derived from the experiment, high energy-resolution spectra of the sun and the galactic center will be taken. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The objective of this research is to develop the mathematical formalism necessary to treat correlative statistics for lattice spaces. Toward that goal the investigators are considering (1) the composite kth neighbor degeneracy problem for indistinguishable particles distributed on one dimensional rectangular lattice space; (2) the occupational degeneracy for dumbbells and lambda-bell particles on saturated and unsaturated, rectangular lattice spaces of higher dimensionality here they are considering dumbbells that may have either indistinguishable or distinguishable ends; (3) the nearest neighbor degeneracy problem for simple, indistinguishable particles distributed on rectangular lattice spaces of higher dimensionality. A secondary objective is to exploit the results of the foregoing research by investigating the consequences of this formalism to chemical and physical systems. Most notably they are considering adsorption processes. The investigators have developed set theoretic arguments that hold the promise of treating successfully a number of problems concerning correlative statistics for lattice spaces. Utilizing this technique they have been able to describe exactly the occupational degeneracy for correlated particles such as dumbbells and lambda-bell particles distributed on lattice spaces of two and three dimensions. The investigators have also utilized these set theoretic arguments to obtain recursion relations

ABSTRACT: (U) Three researchers and one visitor were supported by this grant during this period. Most of the research was in various aspects of reliability, including network reliability, a generalized model of continuous reliability growth, a software reliability model combining the results of several independent inspectors, and a model in which the failure rates for components depend on the working set. Other investigations included Bayesian methods for combining expert opinion, enriched prior distributions for the multinomial distribution, and a new approach to using simulation to estimate first-passage time distributions for Markov chains. Eleven research papers and one Ph.D dissertation were produced during this period. This report summarizes research results and lists publications generated during this period. (Author)

ABSTRACT: (U) In the original proposal the investigators had outlined a long term program for conducting research in knowledge based systems. In particular they proposed to study issues in diagnostic reasoning and in knowledge-directed information retrieval. During the first year most of the progress came in the area of diagnostic reasoning and in the conceptual foundations of knowledge-based systems in general. The investigators also developed an approach to a new type of task: design of mechanical parts. This report summarizes specific progress made in these areas. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The reliability of a structural system at a particular time depends on the damage level in the system. When the damage level exceeds a critical value, then failure occurs. Therefore, it is important to track the damage in a structure. In the present investigation some basic models are proposed for the study of damageable structure response. The models are: a higher order linear differential equation with constant coefficients, and a second order linear differential equation with time varying coefficients. Using a digital computer a blast is simulated, and the response of an inelastic structure is computed. Noise signals are added to these and the results are used to simulate measured input and response. Next, using the simulated input and response, the parameters of the linear models are identified and the linear structure responses are computed. Measures of these responses, including peak displacement and energy dissipated are compared to the simulated response. It is shown that the models accurately simulate inelastic structure response. Moreover, the results of some experiments are included. The experiments show that the energy dissipated in a material specimen is related to the damage level. (Author)

ABSTRACT: (U) Method for statistical estimation of parameters of partially observed stochastic processes and for minimum mean squared error reconstruction of unobserved portions of sample paths (state estimation) were developed. Some of these methods apply to models of random distributions of particles in space or events in time; others apply to Markov processes. Statistical estimators are asymptotically exact even though certain of the unknown parameters are infinite-dimensional. For several classes of processes the problem of simultaneously performing parameter estimation and state estimation was solved. Refined techniques for reconstructing a deterministic signal from hard-limited data were devised. (Author)

ABSTRACT: (U) This is a summary of work accomplished under the grant. The purpose of this effort is to develop realistic algorithms for matrix computations on parallel computers. The research is proceeding in three stages. First, decide on a suitable way of connecting and synchronizing processors for parallel matrix computations. Second, design and build a communications system to realize this network on the ZM08. Third, code matrix algorithms for the system, and experiment with them. In addition, the investigators must install and test the floating-point processors which were requested as part of the initial grant period. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The overall objective of this proposal is to investigate the robustness to departures from independence of methods currently in use in reliability studies when competing failure modes or competing causes of failure associated with a single mode are present in a series system. The first specific aim is to examine the error one makes in modeling a series system by a model which assumes statistically independent component lifetimes when in fact the component lifetimes follow some multivariate distribution. The second specific aim is to assess the effects of the independence assumption on the error in estimating component parameters from life tests on series systems. In both cases, estimates of such errors will be determined via mathematical analysis. A graphical display of the errors for representative distributions will be made available to researchers who wish to assess the possible erroneous assumption of independent competing risks. A third aim is to tighten the bounds on estimates of component reliability when the risks belong to a general dependence class of distributions (for example, positive quadrant dependence, positive regression dependence, etc.). Major decisions involving reliability studies, based on competing risk methodology, have been made in the past and will continue to be made in the future. This study will provide the user of such techniques with a clearer understanding of

UNCLASSIFIED REPORT

ABSTRACT: (U) Methods were investigated for evaluating cumulative distributions of continuous random variables of known moment-generating function by numerical quadrature of a contour integral in the complex plane whose integrand involves that function. Applications so far treated were to the detection of radar signals, both fading and unfading, in receivers with constant threshold or with a variable threshold determined by a measurement of the ambient noise (constant-false-alarm-rate receivers) and to the distribution of the average power of a Gaussian random process. Similar methods were studied for finding the cumulative distributions of positive-integral valued random variables by a numerical contour integration involving their probability generating functions, with application to evaluating the distribution of the number of electrons at the output of a photomultiplier. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The research topics investigated were primarily in the areas of quantization and detection in signal processing. The existence of optimal quantizers was established under very general conditions and convergence properties of sequences of quantizers to optimal quantizers were investigated. A simple and straightforward technique was presented for constructing minimum mean-squared error symmetric uniform scalar quantizers for some common input distributions. The Lloyd-Max algorithm was modified to give a very fast design algorithm for scalar minimum mean-squared error quantization. In the area of detection, a continuous time filter was designed for a discrete time problem and outperformed the corresponding discrete time detector. Detection problems were investigated when both signal and noise were modelled as phi-mixing random processes. Several situations were investigated in which asymptotic relative efficiency is an inappropriate measure of efficiency. In a different area of research, the effects of a form of nonlinear distortion on spectral properties of random processes were investigated. (Author)

ABSTRACT: (U) A logical-timing instruction-level simulator is described for a hypothetical multiprocessor consisting of CRAY-1's connected to a common memory. It is useful for gaining insight into the design of multiprocessor algorithms and for developing high performance algorithms for CRAY processors with instruction sets similar to the CRAY-1. (Author)

ABSTRACT: (U) Silicon nitride can be joined using an oxide glass which reacts to form a phase similar to the grain boundary phase found in hot pressed Si₃N₄. The microstructure and interfacial reactions were studied by scanning transmission electron microscopy and X-ray diffraction. Silicon nitride dissolves in the glass and silicon oxynitride crystals precipitate. The glass also penetrates the Si₃N₄ and is present as enlarged glass pockets in the bulk ceramic away from the joint. The optimal joining conditions were determined to be 1575-1650 C and 30 to 60 minutes. The maximum strengths at room temperature determined by 4 point bend tests of bars joined under these conditions were approximately 460 MPa, regardless of the specific conditions. The strength is related to the joint thickness, reaching a maximum for joint thicknesses of approximately 25 to 35 micrometers. Two fracture mechanisms were identified by SEM. Silicon oxynitride crystals grow across thin joints and the resulting microstructure is strong if few pores are present. Thermal expansion mismatch cracks are present in thicker joints and there are multiple fracture origins. Preliminary attempts to heat treat joints to promote crystallization resulted in vaporization of the glass and a low strength.

ABSTRACT: (U) Aloha-type retransmission control policies have been proposed recently by Hajek and Van Loon which can be implemented on a random access channel with ternary or binary feedback. They have shown that such schemes achieve a stable throughput of $1/e = .3678$ for an infinite-population Poisson arrival model, by using simple first-order recursive retransmission policies. We drive measures of the speed of convergence and steady state accuracy for the local 'model' of these policies. Using these measures, we compare two first-transmission policies, namely IFT and DFT. We extend the policies to cover the Success/Failure binary feedback case, which is not covered in the work cited. Finally, we study the effects of channel errors on the performance of the random access system.

ABSTRACT: (U) Research efforts during this period concentrated on the following topics: (a) Deformation of Solids - work on the topic has progressed to the point where the physical mechanisms of creep can be brought in. (b) Excursions of Markov Processes - Two papers by Salmeron are completed in this area. (c) Stochastic Differential Geometry - Starting with a Brownian motion on a Riemannian manifold, the exit time from a ball is considered. The distribution of the exit time is used to investigate the geometric structure of the manifold. This report summarizes the progress made and lists completed publications resulting from the research. (Author)

ABSTRACT: (U) We outline the essential components of a truly integrated OIS. Then we critically examine four of the existing prototype systems and another suggested design. These systems have the common characteristic of providing a form-based user interface. Then we present a set of requirements for such an OIS.

ABSTRACT: (U) During this period, the investigator intended to investigate alternative approaches for improving searching performance in logic programming systems to a level that would be acceptable in a production system by conducting experiments in the LOGLISP system. Due to incompatibilities between the DEC 10 source computer and the CDC CYBER 760 running under NOS, which was available at Florida State University, as well as the differences between the UCI LISP on the DEC 10 and the ALISP available on the CYBER, it was impossible to bring the LOGLISP system to fully operational status and perform the experiments. ABSTRACT: (U) Much of our work during the previous grant year was concerned with quantization theory. Quantization forms the heart of analog to digital conversion and it is a key element in virtually all of digital signal processing. Although quantization theory has been a subject of interest for many years, much remains to be done in this area. The difficulty in this area is compounded by the fact that some of the commonly held beliefs are actually misconceptions. For example, it has often been assumed in the literature that in the scalar case a minimum mean squared error optimum quantizer for a symmetrically distributed random variable will be symmetric (i.e. the quantization levels will be symmetrically distributed about the origin).

ABSTRACT: (U) The research in this project is motivated by pattern analysis, the study of regular structures in natural and man-made phenomena. Problems of inferring structural representations of observed patterns raise new problems of nonparametric statistical inference. The method of sieves has been developed as a general approach for adapting classical techniques of inference, such as maximum likelihood for estimation, to nonparametric settings. To develop the basic probabilistic models that form the foundation for statistical inference of patterns, characterization results have been obtained that prescribe the kinds of probability models generated by the regularity constraints of pattern theory. The mathematical questions have been studied both by analytical and computational methods. The computer experiments have led to the development of a substantial library of APL programs for mathematical experimentation. Numerous applications are described in the publications from the project. (Author)

ABSTRACT: (U) This work extends to symmetric alpha-stable ($S(\alpha, \beta)$) processes, $1 < \alpha < 2$, which are Fourier transforms of independently scattered random measures on locally compact Abelian groups, some of the basic results known for processes with finite second moments and for Gaussian processes. Analytic conditions for subordination of left (right) stationary related processes and a weak law of large numbers are obtained. The main results deal with the interpolation problem. Characterization of minimal and interpolable processes on discrete groups are derived. Also formulas for the interpolator and the corresponding interpolation error are given. This yields a solution of the interpolation problem for the considered class of stable processes in this general setting. (Author)

ABSTRACT: (U) An analytical model for the generation and redistribution of surface coordinates which is to be used along with the full 3D code, has been developed. This essentially completes the development of spatial coordinates generation around multibodies and particularly around a wing-body combination in the 3D space. Numerical results for some multibody problems have been obtained. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The finitely additive nonlinear filtering problem for the model $y \text{ sub } t = h \text{ sub } t (X \text{ sub } t) + e \text{ sub } t$ is solved when the function h is unbounded and satisfies no growth conditions whatever. (Author)

ABSTRACT: (U) The objective of the research has been to develop engineering methodologies applicable, but not limited, to aerospace automatic control design problems in which there are performance specifications requiring precise control of system behavior in the presence of stochastic disturbances (e.g., wind gusts) and large-but-bounded uncertainties in the dynamical response of the system (e.g., parameter uncertainty, unmodeled nonlinearities, and so forth). A cohesive body of theory has been developed that enables engineers to relate the ability of feedback control systems to meet such specifications directly and quantitatively to the return difference matrix associated with the system's feedback loops. Now results enabling L infinity optimization of returned difference singular value Bode plots promise to be of great value in robust multivariable feedback controller synthesis. Continuing research is currently being aimed at further tightening the links between this theory and the most recent developments of modern stochastic linear optimal control synthesis theory, and extending the results to admit more practical problems, so that this theory may be used more effectively by engineers to efficiently and systematically design the feedback gains that determine a feedback system's return difference matrix. Such results substantially reduce the

ABSTRACT: (U) The purpose of this research was the identification of the critical magnet and storage ring parameters for optimization of the efficiency, power output and gain of gain-expanded storage ring free electron lasers. While previous research had identified the basic properties of these devices, the approximations and simplifications employed in these efforts for solution of the equations of motion had led to some ambiguities which were not readily resolvable within the framework of the model employed. To resolve these ambiguities, a model was developed for the FEL wiggler magnet which permits an exact solution of the equations of motion. Using this model numerical techniques have been employed to identify the dependence of the laser power output, gain, and efficiency on the magnet parameters. (Author)

ABSTRACT: (U) The activities done under the grant for the fiscal year 1982 are summarized. Primary emphasis has been the expansion of the applications of the Gelfand-Levitan formalism to provide examples of potentials for which the Schroedinger equation has unusual spectral properties and thereby generalize the kinds of spectral representation which one can have. The investigators were partially successful in considering a case in which the potential is associated with a non-analytic reflection coefficient and a case in which the impulse response is a square pulse. The latter case may be of interest in providing passive means of convoluting a signal with a square pulse.

ABSTRACT: (U) Air Force support of a Center of Excellence at Stanford University has provided the impetus and core for a major new entity, the Center for Automation and Manufacturing Science (CAMS). The new center draws from two well-known research groups at Stanford: the Robotics Group of Stanford's Artificial Intelligence Laboratory and the Automatic Control Group of Stanford's Department of Aeronautics and Astronautics. Ten professors and some 50 graduate students are participating in CAMS activities. CAMS in turn is the first of a new complex of centers at Stanford involved in the manufacturing enterprise: the Stanford Institute for Manufacturing and Automation (SIMA). Strong industrial interaction is a primary objective of SIMA. In our Air Force program we are focusing on robotic aspects of automation. Our goal is to make fundamental contributions to the underlying set of technologies that will enable the next generation of industrial robots to be far more capable than today's - will enable them to be lightweight, limber, deft, facile, quick, friendly, low-powered, seeing, sensing, thinking machines that can reason and

strategize- can carry out tasks assigned at a high conceptual level. Specifically, our research focus is on fast, precise control of lightweight (flexible) manipulators, sensing, especially optical and tactile sensing. Intelligent systems for robot task management, and computer vision for robot management. We are addressing the question of how to provide manipulator control so good that a whole new generation of manipulators can be developed-manipulators that are much lighter and far more facile than anything today's control systems could stably manage

ABSTRACT: (U) The 1983 International Symposium on Multiple-Valued Logic is the thirteenth meeting in a series of annual symposia devoted exclusively to multiple-valued logic. Ten of the past meetings were held in North America, the other two in Europe. The ISMVL-83 in Kyoto, Japan, is the first symposium to be held in Asia. It is dedicated to the investigation of multiple-valued logic to narrow the gap between theory and practice. Because there are many researchers in Japan and neighboring countries, this symposium offers a unique opportunity for a large number of multiple-valued logic researchers to meet. An Asian conference will encourage the technological development of mainland China, where there are 3000 mathematicians engaged in the study of fuzzy logic. In addition to many speakers, from Japan, we have several newcomers from Thailand, China, and Nigeria.

ABSTRACT: (U) In structural engineering it is imperative to design each system to survive the inputs anticipated over the design life of the structure. Strong motion inputs cause systems to execute nonlinear responses, and during the strong motion responses, structures accumulate damage. Therefore, the capability to model nonlinear responses and to assess the damage level in a structure is essential for optimal design. Techniques for the diagnosis of damage in inelastic structures have been developed. The dissipated energy in mechanical systems is taken as a measure of damage accumulation. Two models for the simulation of damaged structural response have been developed. Both the single-degree-of-freedom and multi-degree-of-freedom systems were included in the analysis. The objective of this study is to use these models to estimate the amount of energy dissipated due to a strong motion input. The results show that structural damage can be predicted, even in the presence of measurement noise. (Author)

ABSTRACT: (U) The objective of this project was to fabricate multiple heterostructure bipolar transistors in semi-insulating GaAs substrates. During the first year of effort, molecular beam epitaxial growth of doped aluminum-gallium arsenide (AlGaAs) gallium arsenide (GaAs) heterojunctions was carried out. GaAs layers were doped n-type with silicon from the background (1E16) up to 2E18 and p-type with beryllium up to 1E19. N-type AlGaAs was grown up to 30% aluminum composition and doped with silicon to 1.5E18. Tools were developed for lateral structuring of transistors such as beryllium ion implantation, reactive sputtering and thermal annealing. Single devices were grown, fabricated by mesa etching and tested. Current-voltage characteristics shows evidence of excess recombination current. (Author)

ABSTRACT: (U) The subject of this investigation has been the Free Electron Laser (FEL), a device which is capable of converting the kinetic energy of a relativistic electron beam into coherent electromagnetic radiation. The investigation focused on two main topics: (1) The FEL operated as an oscillator and an amplifier using variable parameter wigglers. (2) The FEL oscillator operated in conjunction with a storage ring using gain-expanded and phase area displacement wigglers. A summary and details of progress for the period October 1, 1982 - September 30, 1983 are presented.

ABSTRACT: (U) This report describes the application of a large-scale numerical wave solver to the time domain study of seismic wave phenomena in basins typical of the Basin and Range province. The solver uses an explicit finite element algorithm designed for fully vectorized execution on the CRAY-1. Calculations were performed to study the effects of basin edge geometry on reflection and transmission of body and surface waves. Normal and tangential surface traction sources were applied on the model centerline. From the resulting full wave field solution, synthetic seismograms were generated and used to quantify principal phases. In addition, the body and surface wave interaction of two basins separated by a mountain was studied. This model required 120,000 elements and demonstrated that large-scale full wave field calculations are practical on the CRAY-1.

UNCLASSIFIED REPORT

ABSTRACT: (U) The basic objective of this research was to determine the feasibility of the conversion of the Stanford Mark III linac to high-gradient operation to serve as an injector or driver for storage ring and single pass free electron laser experiments. The Mark III single section tests have been generally successful. In particular, it has been observed that the Mark III accelerator sections are capable of operating reliably and stably at high gradient if an appropriate vacuum is maintained in the structure, and if appropriate steps are taken to bake out the adsorbed contamination on the cavity walls. Electrons have also been accelerated in the test section to an energy in excess of 40 MeV.

ABSTRACT: (U) In this document the authors summarize our investigation of the reflecting properties of x-ray multilayers. The breadth of this investigation indicates the utility of the difference equation formalism in the analysis of such structure. The formalism is particularly useful in analyzing multilayers whose structure is not a simple periodic bilayer. The complexity in structure can be either intentional, as in multilayers made by in-situ reflectance monitoring, or it can be a consequence of a degradation mechanism, such as random thickness errors or interlayer diffusion. Both the analysis of thickness errors and the analysis of interlayer diffusion are conceptually simple, effectively one-dimensional problems that are straightforward to pose. In the authors' analysis of in-situ reflectance monitoring, they provide a quantitative understanding of an experimentally successful process that has not previously been treated theoretically. As x-ray multilayers come into wider use, there will undoubtedly be an increasing need for a more precise understanding of their reflecting properties. Thus, it is expected that in the future more detailed modeling will be undertaken of less easily specified structures than those above. The authors believe that their formalism will continue to prove useful in the modeling of these more complex structures. One such structure that may be of interest is that of a multilayer degraded by interfacial roughness.

UNCLASSIFIED REPORT

ABSTRACT: (U) A study employing a combination of hydrogen bubble-wire flow visualization and hot-film anemometry measurements has been conducted to determine the effects sublayer scale streamwise surface modifications on the structure and flow characteristics of turbulent boundary layers. The surface modifications were created using very fine monofilament fishing line of an approximate non-dimensional height of $h^+ = 4$. Spanwise line spacings of $60 < s^+ < 160$ were examined for a Reynolds number range $800 < Re_{sub} \theta < 1650$. The hydrogen bubble-wire studies indicate that the lines appear to act as nucleation sites for low-speed streaks, but the influence of the lines on streak stabilization rapidly diminishes for $y^+ > 10$. Streak spacing distributions and statistics were developed from the visualization data for both modified and unmodified surfaces. These results clearly indicate that the surface modifications did affect the streak spacing characteristics, with the greatest effect of the lines on mean streak spacing distributions and statistics occurring for $s^+ < 100$. However, the visualizations indicate that for $y^+ > 10$ the determined streak spacing distributions and statistics, of an unmodified surface.

DESCRIPTORS: (U) *Turbulent boundary layer, *Flow fields.

ABSTRACT: (U) PASM, a large-scale multimicroprocessor system being designed at Purdue University for image processing and pattern recognition, is described. This system can be dynamically reconfigured to operate as one or more independent SIMD and/or MIMD machines. PASM consists of a parallel computation unit, which contains N processors, N memories, and an interconnection network; Q micro controllers, each of which controls N/Q processors; N/Q parallel secondary storage devices; a distributed memory management system; and a system control unit, to coordinate the other system components. Possible values for N and Q are 1024 and 16, respectively. The interconnection network, control schemes, and memory management in PASM are described. Examples of how PASM can be used to perform image processing tasks are given. In addition, there is a list of 53 publications that describe in detail the research that has been supported by this grant. (Author)

ABSTRACT: (U) This Annual Report presents a summary of the scientific progress and accomplishments on research projects funded by the Joint Services Electronics Program (JSEP) for the contract period from 1 April 1982 through 31 March 1983. It does not contain information regarding accomplishments on research projects funded in other ways. The Joint Services Electronics Program at the Polytechnic is the core of interdisciplinary research in electrical encompassing programs in the Departments of Electrical Engineering and Physics under the aegis of the Microwave Research Institute. The research encompassed by this program is grouped under three broad categories: Electromagnetics, Solid State Electronics and Information Electronics.

ABSTRACT: (U) In the design of a structural system, a test input is sought to conservatively represent an ensemble of measured field inputs. When a structure survives the test input, it is assumed that it would survive the field inputs. The method of shock response spectra is a technique for specifying conservative test inputs, but it has some disadvantages. In this investigation a technique is developed for the specification of test inputs. It is based on the method of least favorable response, and it overcomes some of the shortcomings of the method of shock response spectra. Numerical examples show that the present technique can be used in practical applications. (Author)

ABSTRACT: (U) A study was made of the fluid mechanics of a thrust reverser jet reattaching to an aircraft nozzle afterbody. The problem basically involves the Coanda effect flow of a three-dimensional, incompressible jet to an adjacent axisymmetric, inclined surface. The equations were derived in integral form and programmed for numerical solution for the case of an exhaust flow with no opposing free stream flow. Test data are reported for a scale model of a nozzle afterbody exhausting against a target-type thrust reverser. Data are presented for surface pressure coefficient at various points along the model.

UNCLASSIFIED REPORT

ABSTRACT: (U) Levy and Reid's hypothesis that persons who write using the inverted posture have ipsilateral control of distal limb movements, particularly those involved in handwriting, was tested in three experiments in which asymmetries in the readiness potential (RP) were measured. In the first experiment, each subject executed a self-paced repetitive squeeze. Contralaterally larger RPs were recorded from all subjects, irrespective of handwriting posture. In two other experiments, subjects performed the self-paced squeeze in one condition and wrote a single word repetitively in an analogous condition. Larger RPs were recorded over the contralateral cerebral hemisphere in most inverted-writing subjects in both conditions. Ipsilaterally larger RPs were recorded, however, from some left-handers while writing. These findings suggest that, although control of certain movements may originate from the ipsilateral motor cortex in a small proportion of left-handers, handwriting posture does not index this difference.

UNCLASSIFIED REPORT

ABSTRACT: (U) The evolution of unsteady boundary layers on the line of symmetry of a thin prolate spheroid in uniform motion at constant angle of attack after an impulsive start is studied for a prescribed pressure distribution and results have been obtained for angles of attack ranging from 30 degrees to 50 degrees. The unsteady boundary layer is initially unseparated but develops a region of reversed flow after a finite time. A short time later, the streamwise displacement thickness develops a pronounced peak and leads to a singularity of the same type as that observed by van Dommelen and Shen on a circular cylinder started impulsively from rest.

ABSTRACT: (U) A Kaufman ion source was modified to produce a low energy (30 eV) high current density (3 mA/sq cm) O⁺ and O₂⁺ (O⁺/O₂⁺) ion beam at an optical surface being coated with SiO₂. Films of SiO₂ were deposited with O⁺/O₂⁺ ion bombardment at low energy (30 eV) and at high energy (500 eV). Application of the ion-assist technique has the following features: (1) Durable coatings can be produced at low substrate temperature; (2) Film stoichiometry is improved, particularly for low energy bombardment; (3) Hydrogen content of the film is reduced under certain conditions of bombardment; and (4) Stress and structure of SiO₂ films are not greatly affected by ion bombardment. (Author)

ABSTRACT: (U) A theoretical study of the possibility of finite momentum pairing in one- and two-dimensional superconductors was carried out. When the effects of zero momentum pairing, finite momentum pairing, and a charge density wave were simultaneously considered for a one-dimensional system, it was found that the relative phases of the complex gap parameters for each of the three types of order were important. The resulting energy gap was obtained, and the nature of the ground state was examined and found to depend on the values of the effective interaction coupling constants. For the two-dimensional system, it was shown that analogous to previously known results in one dimension, the binding energy of electron pairs, as a function of momentum, has a relative maximum at momentum greater than twice the Fermi momentum. UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Prepared in cooperation with New York Univ., N.Y. Courant Inst. of Mathematical Science and Kernforschungsanlage Juelich, Germany, F.R. Institut fuer Festkoerperforschung.

ABSTRACT: (U) The authors describe the results of Monte Carlo computations of the coherent phase diagram (in the temperature-composition plane) of ordering binary alloys on a face-centered cubic lattice. Results on long- and short-range order parameters as well as ordering energies are also given. They consider the system with nearest neighbor interaction in the grand-canonical ensemble (equivalent to an Ising antiferromagnet in a magnetic field) as well as in the canonical ensemble (fixed composition). Results with next-nearest neighbor interaction are also given, and for both models a comparison with other available predictions is made, particularly with the cluster-variation method. While the latter is found to be quite accurate at stoichiometric composition, it appears to do less well in the more general case. The tetrahedral approximation of the cluster variation method predicts a topology of the phase diagram, in the case of nearest-neighbor interaction different from the computer simulations. Some consequences for the interpretation of the behavior of

UNCLASSIFIED REPORT

ABSTRACT: (U) Relativistic broadening of absorption (or emission) lines near cyclotron resonance in a warm plasma is investigated using the linearized relativistic Vlasov-Maxwell system. The unperturbed state is assumed to be isotropic, but not necessarily Maxwellian. The expansion parameter is $\eta = v \text{ sub } e/c, v \text{ sub } e$ being the electron thermal speed. It is assumed that the wave frequency, plasma frequency, and cyclotron frequency are all comparable in magnitude, and the refractive index $n = O(1)$. The parameter $\alpha = \eta/n$ is of arbitrary order, thus the results are uniformly valid for all values of oblique propagation angles, although the relativistic effects are negligible for $\alpha \ll 1$. The dielectric tensor is reordered, and the dispersion relation appropriate for this problem is derived to the lowest significant order in η . The results are expressed in terms of the readily calculable (generalized) plasma dispersion function Z . In the Maxwellian case the results are algebraic in Z , and unlike the previously published results, they do not involve infinite integrals or series imposed on Z , thus leading to simple and efficient evaluations. The case of perpendicular propagation is obtained by taking the large α limit. Some inconsistencies in the literature dealing with the extraordinary mode are resolved. (Author)

ABSTRACT: (U) A comparison of the optical transform versus the hardware Fourier transform was made for two input functions: a rectangular aperture and a six-pointed star design. The optical transforms were modified using sharp and smooth lowpass as well as highpass filters. The results were compared against those obtained using the array processor hardware at the Brooks Air Force Base, School of Aerospace Medicine. The ringing observed in the lowpass filtered results of the array processor was simulated by the optical methods. However, certain asymmetric in the hardware ringing data were not observed optically. A discussion of the ringing and how to eliminate it is also presented. (Author)

ABSTRACT: (U) Research was conducted and directed in the area of stochastic processes by three Principal Investigators and their associates, and in estimation in statistical models. The main areas of research activity for each Principal Investigator and co-workers are as follows: (1) Asymptotic optimal quantizers, complex symmetric stable variables and processes, prediction and representation of stable processes, nonparametric spectral density estimation for stable processes, delayed delta and pulse code modulation; (2) Feynman integrals, stochastic nonlinear filtering, stationary random fields, stochastic differential equations and diffusion approximation models for neuron activity, white noise and generalized Brownian functionals, stochastic Radon transforms, splicing of measures; and (3) Extreme values of stationary stochastic sequences and processes, dependence structure of stochastic processes, extremes of non-stationary normal sequences, estimation of point process intensities.

UNCLASSIFIED REPORT

ABSTRACT: (U) Theoretical spectra of thermal cyclotron line emission from solar active regions are presented for two frequency bands available at the Very Large Array (VLA). VLA synthesis maps of three active regions at 1380, 1540 and 1705 MHz are then presented. The maps of two of these regions show significant changes in the brightness temperature within these narrow frequency ranges. We show that these changes may be attributed to thermal cyclotron line emission in small regions ($\theta = 10$ ins to 30 ins) where the magnetic field is relatively constant with $H = 125$ -180 Gauss. An alternative interpretation, involving height-dependent variations in the physical conditions may also explain the changes in one of these regions. The potential to study coronal magnetic fields using VLA observations of cyclotron lines is also discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) Numerous tasks have been completed in developing measurement and prediction techniques for accurately determining the fluid-structure-interaction forces on labyrinth seal rotors. The best facility has been designed, fabricated, and assembled; the drive mechanism and instrumentation system have been tested further. Various improvements to the test apparatus have been implemented. Also, the development of two basic computational approaches for predicting seal rotor forces has been successfully completed. These consist of an improved but approximate analytical model and an extensive computer program incorporating the complete Reynolds-averaged Navier-Stokes equations. The latter model solves finite difference equations in predicting the two-dimensional (axisymmetric) compressible flow in a concentric-rotor labyrinth seal cavity. Details of a corresponding incompressible flow prediction are presented and discussed. The final numerical model will allow prediction of the desired three-dimensional, eccentric-rotor flow field and the associated rotordynamic forces.

ABSTRACT: (U) Progress on real-time 1-D and 2-D spatial light modulators, optical systolic array processors, optical image processing, and distortion-invariant pattern recognition are reported. Our real-time spatial light modulator research concerns the Soviet PRIZ device and bulk acoustic-optic transducers. Novel features detailed for the Soviet device include: uniform and directional spatial filtering and static image suppression or change detection. Systolic array processor research includes a new frequency-multiplexed architecture, realization of singular value decomposition and matrix decomposition algorithms. Optical image processing and pattern recognition research received major attention. A new class of nonlinear local operators including the Sobel operator were described and demonstrated. New optical feature generation techniques for distortion-invariant pattern recognition were developed. These include the generalized optical chord transformation. Our primary distortion-invariant pattern recognition research addressed synthetic discriminant functions with attention to two new efficient calculation techniques. The performance of synthetic discriminant functions for multi-class distortion-invariant pattern recognition, and initial noise performance of this optical pattern recognition algorithm. (Author)

1983.

ABSTRACT: (U) The problem of extrapolation of scene-limited functions was investigated with an eye towards accommodating noisy measurements, and incorporating all available a priori information. An iterative projection approach was introduced, aimed specifically at removing a priori information and constraint incompatibility due to noisy measurements. Soft frequency domain measurement constraints and soft scene domain limitation constraints were proposed, and can alleviate convergence problems that occur when the imposed information is not compatible. The soft frequency domain measurement constraint specifically allows the algorithm iterate to deviate from the noisy measurements, in recognition of the fact that the measurements were noisy, and they should therefore not be imposed as an absolute or hard constraint. The resulting alternating projection algorithm was shown to correspond to a non-expansive operator so that many solutions exist, all of which satisfy the a priori information and constraints. UNCLASSIFIED REPORT

ABSTRACT: (U) We have observed a radio burst from the main sequence (M4.5e) star AD Leo at 1400 MHz from 0536 to 0556 UT on 1983 February 1 at the Arecibo Observatory. A rapid sequence of highly polarized spikes was observed during the gradual rise of a longer lasting, unpolarized event. The maximum flux density of the spikes was $S(\text{max}) = 130 \text{ mJy}$, and they had rise times less than or approx. 200 ms. The spikes were all 100% left hand circularly polarized with an instrumental uncertainty of 5%. The rise times provide an upper limit to the linear size L less than or approx. 6×10 to the 9th power cm for the emitter. Provided that the source is symmetric, it has an area that is less than three hundredths of the star's surface area. In this case, the lower limit to the brightness temperature of the spikes is 18 greater than or approx. 10 to the 13th power K. The high brightness temperatures and high degrees of circular polarization are explained in terms of electron-cyclotron maser emission at the second harmonic of the gyrofrequency in longitudinal magnetic fields of strength H1 approx. 250 gauss. The unpolarized gradual component did not exhibit any rapid fluctuations, and it was entirely analogous to the thermal emission of solar bursts. (Author)

ABSTRACT: (U) A theoretical method for defining texture
measures was defined by Connors and Vasquez. The use of
this method requires a perceptual ranking which can be
used to rank the relative visual differences among a set
of texture pairs. This report describes the theoretical
development and an implementation of such a perceptual
ranking. This perceptual ranking is called the law of
comparative judgement. It was developed by Thurstone. It
allows n things to be ranked (scaled) based on pairwise
responses obtained over all possible combination of n
things taken two at a time.

UNCLASSIFIED REPORT

ABSTRACT: (U) A theoretical method for defining texture measurements was defined in previous works. To implement this method, it is necessary to have the ability to generate textures. Two texture generation procedures are proposed: first, a modified Gagalowicz generation procedure and second, a Markov texture generation procedure. The objective of this report is to describe the implementation of the latter of these generation procedures.

IDENTIFIERS: (U) Markov texture generation program, Markov chains, Texture generation, PE61102F, WUAFOSR2304A2

ABSTRACT: (U) During this period, research continued in the area of numerical solution of the incompressible Navier-Stokes equations. In particular, the following topics have been addressed: (1) The question of achieving stable discretizations of the incompressibility constraint; (2) The problem of obtaining accurate solutions in the limit of large Reynolds numbers; and (3) Devising efficient numerical solution algorithms for solving the nonlinear algebraic systems of equations arising from the discretization step. A necessary condition for convergence of the discrete approximation was obtained. A major result achieved has been to show that many often used low order element pairs are, in fact, unstable in the sense of this criterion. In addition, new simple low order element pairs were introduced and proved to be stable. Concerning the second topic noted above, the investigator has taken an approach based on the idea that h (the discretization parameter) needs to be small only in certain locations, namely in boundary layers. Finally, solving the algebraic systems which arise from the discretization remains a major difficulty. Two new approaches have been developed, one dependent on time marching to the steady state limit, and the other based on an adaptation of a method used in structural mechanics to the fluids case. Four new scientific papers have been generated in the report period, to be published in the referred literature. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Aluminum alloys exhibiting high strength
and improved creep resistance at elevated temperatures
offer the potential for lower weight and reduced cost in
aerospace components. Powder processing, involving
controlled atomization and hot consolidation, provides a
means for fabricating candidate alloys; the
microstructure consists of a stable fine-scale uniform
dispersion of intermetallics in the aluminum matrix.
Retention of elevated temperature strength has been
demonstrated in a P/M Al-Fe-Ni alloy. Atomized powder is
characterized by a duplex microstructure of fine and
coarse regions of FeNiAl9 (Vf approximately = 0.3) in the
aluminum matrix. The fine microstructure is harder than
the coarse microstructure and is table up to
approximately 350 C, above which its hardness decreases
rapidly. There is a gradual coarsening and decrease in
hardness of the initially coarse regions with increasing
temperature. The duplex microstructure is carried over
into the hot pressed and extruded material. Changes in
microstructure and hardness of the extruded material
during elevated temperature exposure are similar to those
occurring in the powder form. Hot tensile test data (up
to 400 C) indicate that the extruded material retains
approximately 60% of its ambient strength up to
approximately 250 C with ductility approaching 10%. This

ABSTRACT: (U) The modeling of discrete-time stationary communication channels with memory was investigated. The approach was to develop distance measures to quantify the degree to which one channel or model approximate another and then to characterize the class of channels that can be well approximated by various types of models. A variety of channel distances were investigated. The results provide characterizations of the classes of channels approximable by finite memory models, primitive models, and finite state indecomposable models. The concept of channel entropy, which is the minimum amount of randomness needed to simulate a channel, was discovered. The results apply to both discrete and continuous alphabet channels. (Author)

ABSTRACT: (U) Progress is reported in studies of key chemical and physical processes by which molecules in excited electronic states dissipate their excess energy. Many of these energy relaxing mechanisms and related molecular motions are so extremely rapid, especially in liquids, that they require special techniques for their study. To this end sophisticated picosecond laser systems were constructed which enable detection of transient absorption, emission and scattering events on the picosecond time scale. Spectroscopic methods are used to address two important classes of chemical problems. One is the key role played by excited state intramolecular charge transfer processes in opening up new pathways for chemical change, energy transfer and decay in molecular systems. The second area is aimed at the key aspect of chemical reactions, namely the identification and study of the properties of the short-lived chemical intermediates occurring in chemical reactions.

ABSTRACT: (U) The optically-addressed microchannel
spatial light modulator (MSLM) is a versatile, real-time
optical signal- and image-processing device that exhibits
high optical sensitivity and high framing speed. It
consists of a photocathode and a microchannel plate in
proximity focus with an electro-optic crystal plate. A
planar electron acceleration grid is often placed between
the MCP and the electro-optic plate. The electro-optic
plate carries a high-resistivity dielectric mirror on one
side and a transparent conducting electrode on the other.
The fundamental operating characteristics and material
limitations of the device are discussed. The role of
secondary electron emission in the operation of the
device is stressed and some of the write, cycling, and
readout modes and their limitations are described. In
addition, the limitations of the inherent space-domain
image-processing operations of the device are discussed.
In the final section, the report summarizes some of the
key results on the application of the MSLM to the problem
of high resolution, all-optical, adaptive wavefront phase
compensation for communication and imaging through the
earth's atmosphere. (Author)

ABSTRACT: (U) The addition of steel fibers to concrete-type materials has been shown to improve many of the engineering properties of those materials. Notable among them is an enhancement in the tensile strength of an otherwise weak and brittle material. Although much is known about the tensile strength of steel-fiber reinforced concrete (SFRC) under one-dimensional state of stress, little is known with regard to the strength behavior under multi-dimensional tension-compression loading. This is attributed to a lack of suitable equipment for simultaneously applying tensile and compressive stresses. The research program described herein is focused on developing such equipment to study the behavior of SFRC under combined loadings. A review of the state-of-the-art research on the tensile strength of SFRC is given and a review of various methods of applying tensile stresses to concrete specimens is presented. The problem is to be overcome in applying a pure principal tensile stress are discussed.

ABSTRACT: (U) The splitting of the spin doublet of the
1s 2p ($m=+1$) transition of the hydrogen-like silicon
donor in n-GaAs has been observed as a function of
applied magnetic field at low temperature. The splitting
of the spin doublet increased with increasing magnetic
field intensity. The dependence of the splitting on
magnetic field intensity was not only larger than linear
but was also larger than quadratic dependence in
agreement with theory.

UNCLASSIFIED REPORT

ABSTRACT: (U) Expert systems are built to solve problems in application areas for which 'good' algorithms are not known. These systems consist of a global data base of assertions, a set of rules that represent small bits of an expert's knowledge, and a control strategy for applying the rules to the assertions. Agendas are used to make the control strategy more efficient. Efficiency can be further increased by indexing the rules and assertions in various ways, one of which is frames. A system for deriving formal specifications from natural language requirements is presented as an example. (Author)

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Prepared in cooperation with Tufts Univ., Medford, MA. Dept. of Chemical Engineering.

ABSTRACT: (U) Investigated is the durability of the joints (Alpha-A1203/Gamma-APS/PE) in wet environment as a function of the gamma-APS thickness, dehydration of gamma-APS prior to joint formation and redrying the joint after a certain exposure. The joint strength measured by peel strength is found to decrease with exposure time in wet environment more rapidly in water than in 100% RH. With exposure time, the debonded area increases from the edges toward the central area of the joint. Relatively thin gamma-APS treatment on alpha-A1203 appear to provide more durable joint than thicker gamma-APS treatment resulting in an optimal thickness in the range of 0.3 approx. 1% gamma-APS concentration level. Dehydration of gamma-APS lead to more durable joint with an optimal condition found between 1 approx. 2 days of dehydration at 100 deg C in vacuum. Regardless of the gamma-APS thickness and dehydration history, the failure in debonded area seems to occur by the hydrolysis of gamma-APS near alpha-A1203 side and by the deformation of polyethylene (cohesive failure) in the peeled area, as characterized by SEM and ESCA. The debonded area in the dried joint recovers little strength but in the bonded central areas, the

UNCLASSIFIED

DTIC REPORT BIBLIOGRAPHY SEARCH CONTROL NO. EVP02F

AD-A136 089 CONTINUED

AD-A136 088 23/5 9/1

strength is largely recovered, characterized by the extensive deformation of polyethylene. Diffusion of water in gamma-APS near alpha-A1203 side rather than PE side can explain at least qualitatively most of the observed trends. Comparisons are made for the effects of gamma-APS thickness and dehydration on the durability in wet environment and adhesion promotion in dry environment as well as on their respective failure mode.

ABSTRACT: (U) Document describes a Ag-Li compound cathode for the longitudinally d.c. excited, low power, CO2 waveguide laser. Discharge tube results with this cathode produced an acceptable gas composition over a period of 1000 hours. The sputtering rate was quite low and, most importantly, the sputtering products did adhere quite well in the form of a thin film on the closest, cooler surfaces. A laser, using two of these cathodes, still produced 72% of its initial power output after 9200 hours of continuous service. Failure analysis indicated internal mirror damage on one of the mirrors, most likely due to improper selection of the dielectric top layer. Considerably more sputtering took place in the laser than in the discharge tube due to a laser cathode temperature that was too low. In parallel with these efforts we have started to investigate the life potential of the transversely r.f. excited waveguide laser. Preliminary results are quite encouraging. These tests were carried out over periods close to 3000 hours and indicate that proper selection of electrode materials is quite important. A wave guide laser with one of the waveguide sides made from a platinum alloy still yields 74% of its initial 2.85W after 5200 hours of continuous operations.

UNCLASSIFIED REPORT

ABSTRACT: (U) The data base previously developed for multicomponent Slalon Ceramic phase diagrams has been expanded to cover Ce2O3, BaO and Y2O3 additions. Isothermal sections in the MgO-Si3N4-SiO2, Y2O3-SiO2-SiN4 and Ce2O3-SiO2-Si3N4 system near 2000 K were computed and compared with limited experimental data. The trajectory of ordering temperatures for A2/B2 and B2/D03 reactions has been computed along the Fe3Si-Fe3Al composition path in the BCC of the Fe-Al-Si system and compared with experiment. The two phase (fcc & bcc) fields for ordered phases in the iron-aluminum-nickel, iron-aluminum-manganese, and the iron-nickel-manganese system between 700 C and 1200 C. Construction of a data base for fluoride systems consisting of systems containing ZrF4 which are employed to synthesize fluoride glasses has been initiated and used to calculate the composition of maximum liquid stability in the ZrF4-LaF3-BaF2 and the ZrF4-BaF2-NaF systems where glass formation has been observed. The calculations have been extended to consider the effects of AlF3 additions on the glass compositions with good results. An analysis of the titanium-carbon-nitrogen system coupling the thermochemical and phase diagram data was performed to calculate the ternary phase diagram and thermochemical properties over a range of temperature.

ABSTRACT: (U) This is the Final report on a program to study the properties of phase conjugate optical resonators. Laser oscillation was achieved using both atomic sodium and photorefractive BaTiO3 in four-wave mixing geometry as a phase conjugate resonator. Spectral and transverse mode characteristics were measured. A self-pumped phase conjugate mirror was also used in an oscillator and a computer code developed to model power output and transverse mode profile. Aberration correction was demonstrated. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Primary effort was devoted to the study of oxygen reduction using water-soluble iron and cobalt porphyrins, namely, iron and cobalt tetrakis (N-methyl-4-pyridyl)porphyrin. These porphyrins with the metal in the +3 oxidation state can be electrochemically reduced to the divalent state which can then react with oxygen. In the case of the iron containing porphyrin, oxygen was reduced at a bimolecular rate of ca. 1×10^{-10} to the minus 7th power 1/m/s to hydrogen peroxide which was then reduced rapidly to water. A mechanistic scheme was postulated for the reduction and using experimentally determined parameters, current-potential curves were simulated. Good agreement between the experimental and computer calculated current-potential curves supported the proposed scheme. Cross-correlation between optical, electrochemical and magnetic circular dichroism results have provided axial ligation, dimerization and spin state information of the ferric and ferrous tetrakis (n-methyl-4-pyridyl)porphyrins. Glassy or graphitic carbon electrodes were rendered catalytic by the incorporation of iron porphyrin derivatives infinity e.g. iron tetra-(o-amino-phenyl)porphyrin and iron tetra-(N(2-hydroxyethyl)pyridyl)porphyrin summation in thin polymeric films adhering to the carbon. The extent of oxygen reduction to hydrogen peroxide and water depended on the amount of iron porphyrin.

ABSTRACT: (U) This report describes further progress in the development of fiber optic Sagnac loops for inertial rotation sensing (i.e., fiber gyros). The report consists mainly of two sections. The first section describes work on developing a bidirectional optical amplifier for use in fiber optic sensing loops while the second section deals with limits on rotation sensitivity due to fiber scattering and noise statistics of optical sources.

UNCLASSIFIED REPORT

ABSTRACT: (U) A finite element formulation and algorithm for the nonlinear analysis of the large deflection, materially nonlinear response of impulsively loaded shells is presented. A unique feature of this algorithm is the use of a bilinear four node quadrilateral element with single point quadrature and a simple hourglass control which is orthogonal to rigid body modes on an element level and does not compromise the consistency of the equations. The geometric nonlinearities are treated by using a corotational description wherein a coordinate system that rotates with the material is embedded at the integration point; thus the algorithm is directly applicable to anisotropic materials without any corrections for frame invariance of material property tensors. This algorithm can treat about 200 element-time-steps per CPU second on a CYBER 170/730 computer in the explicit time integration mode. Numerous results are presented for both elastic and elastic-plastic problems with large strains that show that the method in most cases is comparable in accuracy with an earlier version of this algorithm employing a cubic triangular plate-shell element, but substantially faster. ABSTRACT: (U) Volumes II and III together give an overview of the state of the art in Computing Complex Turbulent Flows in 1981 using the data base established for this purpose in Volume I. The materials are intended to be complete in the sense of providing all elements necessary for understanding the state of the art. Thus, Volumes II and III include: (i) taxonomies that organize the flows, methods of modeling, numerics; (ii) comments by non-computers (the reporters) on results for each class of flows; (iii) discussions carried through to closure and carefully edited; (iv) samples of recent high-level research computations that are currently beginning to provide information of aid to turbulence modelers; (v) an overall evaluation of the state of the art by a distinguished committee of nine workers in the field; (vi) an opinion by the leading editor on the question of 'universality' of turbulence models, potential roads toward further progress, and discussion thereof by others (vii) all computer output compared with data, case by case; (viii) comments by computer groups on experiences

ABSTRACT: (U) The objective of this workshop on optical thin films was to generate a list of basic research efforts which should be pursued in thin film processing techniques and thin film diagnostics which would lead to the development of more damage resistant, more predictable and repeatable thin film coatings which would exhibit long life and stable performance. A group of invited papers covering laser damage, surface preparation, film microstructure, deposition techniques and diagnostics were presented. Discussion of the research needs to advance basic understanding and improvement of optical thin films is summarized, and a prioritized research program which has been generated by the Workshop Advisory Committee is given.

ABSTRACT: (U) The major goals of this research have been to develop diagnostic spectroscopic methods for measuring spatial/temporal temperatures of combustion flames and plasmas and to develop sensitive, selective, precise, reliable, rapid spectrometric methods of trace analysis of elements present in jet engine lubricating oils, metallurgical samples, biological materials, and automobile and other engine exhausts. The diagnostic approaches have been based upon the measurement of pulsed laser excited fluorescence of seeds, such as In, Ti, Pb, etc., introduced into the flames, plasmas, or hot gases or in the case of flames, the measurement of natural flame species as OH. Because of the excellent fluorescence signal to noise ratios, it has been possible to measure temperatures of combustion flames for volumes smaller than 1 cu mm and for single laser pulses of a few nanoseconds. The technique with the most promise for use in combustion flames and in reactors is based upon thermally assisted fluorescence of an externally introduced seed as Ti and In or of an internal species as OH. By exciting the species with a dye laser and measuring the fluorescence from energy levels thermally excited from the laser excited state, the flame (plasma) temperature can be readily measured (\pm or $-$ 10 C) for a volume < 1 mm³ and for a single laser pulse.

ABSTRACT: (U) A general system of vertically integrated equations, including a dust concentration equation, has been derived. The boundary layer is divided into a constant flux layer, a transition layer, and an inversion layer. A novel feature of the model is the inclusion of equations to predict temperature and moisture lapse rates. The inversion height is also a function of time. A simplified version of the model has been tested with respect to its ability to predict the evolution of the inversion height and of the dust concentration. The results show very reasonable evolutions. The inversion height is lowest in the early morning, reaching a maximum in the late afternoon. The dust concentration near the ground is highest in the early morning, when the air is most stable, and lowest in mid-afternoon, when the atmosphere is least stable. These results, obtained for various particle sizes, are highly dependent upon the form of the mesoscale vertical velocity at the base of the inversion. (Author)

ABSTRACT: (U) High temperature alloys in order to maintain their strength during long time exposure at high temperatures must have stable microstructures. The dispersed phase coarsening rates in the A1-7.5Fe-3.5Ce and A1-10Fe-1.5Mo-1V alloys, developed for high temperature applications, were compared at 475 and 575 C. To the extent that the average intercept length cubed, L^3 , is a linear function of time during isothermal aging, after an initial transient, the particle coarsening obeys the Lifshitz-Slyozov-Wagner theory. The interfacial energies estimated from the coarsening rates using the theory of particle coarsening show that the interfaces between the particles and matrix are high energy incoherent interfaces. The dispersed particles in the A1-10Fe-1.5Mo-1V alloy coarsen faster at both temperatures than the particles in the A1-7.5Fe-3.5Ce showing that the latter alloy is more stable at these temperatures. Since the diffusion in diffusion controlled coarsening usually occurs by a vacancy mechanism, plastic deformation should increase the rate of particle coarsening since plastic deformation increases the vacancy concentration. This has been confirmed in combined creep and coarsening studies with the A1-7.5Fe-3.5Ce alloy.

UNCLASSIFIED REPORT

ABSTRACT: (U) In order to clarify the effects of vibrational excitation on shock-wave transitions of weak, spherical N-waves, which were generated by using sparks and exploding wires as sources, the compressible Navier-Stokes equations were solved numerically, including a one-mode vibrational-relaxation equation. A small pressurized air-sphere explosion was used to simulate the N-waves generated from the actual sources. By employing the random-choice method (RCM) with an operator-splitting technique, the effects of artificial viscosity appearing in finite-difference schemes were eliminated and accurate profiles of the shock transitions were obtained. However, a slight randomness in the variation of the shock thickness remains. It is shown that a computer simulation is possible by using a proper choice of initial parameters to obtain the variations of the N-wave overpressure and half-duration with distance from the source. The calculated rise times are also shown to simulate both spark and exploding-wire data. It was found that, in addition to the vibrational-relaxation time of oxygen, both the duration and the attenuation rate of a spherical N-wave are important factors controlling its rise time. The effects of the duration and the

UNCLASSIFIED REPORT

ABSTRACT: (U) Quantum mechanical studies, including both ab initio configuration-interaction expansions and density functional calculations, have been carried out to examine the electronic structure, radiative lifetimes and collisional branching ratios for molecules of importance in studies of electronic transition lasers. These studies have included an analysis of the energetics of Mg/MgO excitation transfer reactions, the spectroscopy of the low-lying electronic states of the I2 and I3 molecules and the mechanisms of the I2/O2 1 Delta g dissociation kinetics. In addition, a study of the electronic structure of the NaMg system was carried out to evaluate its potential as a excimer laser.

SUPPLEMENTARY NOTE: Prepared in cooperation with Stanford Univ., CA, Dept. of Computer Science.

ABSTRACT: (U) The object of this research is the development of programming knowledge for the synthesis of concurrent programs. In this final report the authors describe techniques for synthesizing efficient parallel structures from high level specifications of a problem. These structures contain collections of trees interconnected in various ways. They examine an apparently diverse group of problems and show that they all have properties in common that allow these syntheses to be performed using only a few synthesis rules. Also explored are some alternative syntheses for some structures. Some of the synthesis paths use transformation rules designed to produce parallel structures containing multidimensional lattices. These lattices are then transformed into structures containing trees in some cases. In other cases the lattice structure is better and is retained. In yet other cases the lattice structure is modified to make a better lattice structure. (Author)

ABSTRACT: (U) An investigation of the interaction of electrostatic waves launched by a slow wave structure with a magnetized plasma is made. The characteristics of the electrostatic waves and the electron dynamics are studied experimentally. Of primary experimental interest is the measurement of the electron energy distribution and the rf-induced electron flux along the background magnetic field. This interest is motivated by a need for a more complete understanding of interaction of plasma with a slow wave electrostatic field which is of importance for rf-heating and rf dc current drive in plasmas.

ABSTRACT: (U) A ring resonator 4 cm in diameter was fabricated and tested for sensing applications. A finesse of four was measured, and agreed with measured coupling efficiency and losses. Techniques have been developed to reduce the loss and from our measurements we predict that a finesse of more than 20 should be easily achievable in an interferometer 4 cm in diameter. This device has a wide variety of applications from temperature and wavelength sensing to inertial rotation sensing. Further refinements which will produce a high finesse resonator are the fabrication of a single mode ring and using specially prepared optical glass substrates. Operation at wavelengths longer than 0.63 micron will also improve the performance. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The concept of the Resilient Modulus of Subgrade Reaction, $K_{sub R}$, developed to account for the stress dependent behavior of typical fine-grained subgrade soils. This new subgrade support parameter is defined as plate pressure/resilient deflection in an impulse plate load test simulated using finite element program ILLI-PAVE. The resilient modulus of subgrade reaction, $K_{sub R}$, is expressed in the same units as the standard static modulus of subgrade reaction, K , but the value of the former is significantly higher. This indicates increased stiffness in response to rapidly moving loads. The finite element model presented in this report is a modified and expanded version of ILLI-SLAB, developed in 1977 for the study of jointed, slab-on-grade pavements. A number of modifications to the original code are described. The most important of these is the incorporation, through an iterative procedure, of the deflection dependent Resilient Modulus of Subgrade Reaction ($K_{sub R}$). This parameter is considered more appropriate in modeling nonlinear subgrade response to rapidly moving loads. Other changes include: generation of contour plots of system response; introduction of specification of loaded areas in terms of global coordinates; and, free-form input capability. To illustrate the impact of these innovations, results from several demonstration runs are summarized. The major

AD-A135 836

effect of the proposed model is due to the higher values of $K_{sub R}$, compared to the commonly used static K .

ABSTRACT: (U) In July, 1983, a 2 1/2 day meeting on
nitration chemistry was held at SRI International in
Menlo Park, CA. The sponsors of the meeting were ARO and
AFOSR, and 24 papers on the various aspects of nitration
were presented. The 71 attendees heard presentations on
the mechanism of aromatic nitration, including
discussions of the possible participation of electron
transfer, and advanced studies in ipso nitration. Also
included were presentations of polynitroaromatics and
polynitropolyhedranes. (Author)

ABSTRACT: (U) In the first research category, two different areas were studied: Analysis of laminar duct flows, and study of laminar and turbulent separated flows. These studies were aimed at acquiring a better understanding of isolated physical phenomena significant to turbomachinery applications via the use of appropriate model problems. The second research category is aimed at obtaining flow-dependent computational grids efficiently so that critical regions can be accurately modeled. The final research category includes the analysis of numerical methods, with the goal of improving the efficiency and accuracy of the various methods developed and implemented. Preliminary fine-grid marching solutions were obtained in the entrance region of the duct for eight different duct configurations. Streamwise separation was examined, using the model problem of laminar flow through a constricted asymmetric channel. True transient results were obtained for several flow configurations with extremely fine grids, so as to provide benchmark solutions which can permit assessment of other solutions obtained using approximate methods. Turbulence modeling was pursued, with the wall region being described by low-remodeling. Although the wall region can be modeled more accurately by this method, the fine grids required retard the convergence rate of the

AD-A135 762

AD-A135 762

approximate factorization method used. Flow-dependent grids were generated for a 1-D nonlinear viscous Burgers' equation. For the first time, accurate results were computed using totally central-difference schemes for Re up to 10,000. Finally, in the last category, in the area of semi-implicit methods, a multi-grid method was developed to provide fine-grid solutions for the Neumann problem.

ABSTRACT: (U) A three-dimensional finite element procedure is developed for the analysis of three-dimensional transonic flows and applied to the analysis of wing-body combinations. A finite element grid generation scheme for three-dimensional bodies with complex geometries is presented. The design of efficient, body-fitted computational grids with isoparametric mappings, as well as the application of higher-order finite elements in analyzing transonic potential flows are investigated. Two different computational grids were designed and studied with a numerical scheme based on the density upwinding in the supersonic regions. A pseudo-steady state solution. It is concluded that the grid generation scheme is quite flexible and efficient for generating solution adaptive grids and providing local refinements in the sensitive flow regions. Also, it is shown that the employed numerical scheme with higher-order elements at flow regions of high gradients produced results which compare favorably with experimental data. (Author)

ABSTRACT: (U) The maximum extent of unintentional Si incorporation has been defined for deposition of GaAs and InP by both the chloride and hydride processes. The extents were determined on the basis of constrained chemical equilibrium being achieved in the CVD reactor. The input species consisted of the input gas components and excess condensed phases of the group III source material and quartz reactor wall. The work performed included incorporation of a novel pseudo-steady state constraint for the liquid source, identifying vapor species not included before, and establishing the vapor composition relation to the point defect structure. The results indicate that Si incorporation levels can be significant. In general, the activity of Si was less in the hydride system and with the compound source in the chloride system. Furthermore, the activity of Si decreased significantly with temperature, small additions of H₂O, HCl or VC13 to the mixing zone, and replacing the H₂ carrier gas by an inert in the chloride system. However, the activity of Si displayed a maximum with system pressure and was somewhat insensitive to input composition. Reviews of the literature are included for

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Presented at the AIAA Aerospace
Sciences Meeting (21st) 10-13 Jan 83, Reno, NV.ABSTRACT: (U) For several years the authors have been
evaluating and developing numerical simulation schemes
for compressible, two dimensional inviscid or viscous
flows in turbomachinery cascades. Numerical schemes
considered, all originally classified as time-marching
schemes, include: 1) implicit approximate factorization
schemes; 2) explicit schemes due to McCormack; 3)
explicit central difference schemes; and 4) the multi-grid
scheme of Ni. As we develop these schemes we came to
believe that the accuracy of computational results is
relatively insensitive to the numerical algorithm chosen
but highly sensitive to implementation details such as
boundary conditions, consistent flux balancing, grid
resolution and numerical smoothing. To illustrate our
viewpoint, we present an examination of the relationship
between a flux balancing interpretation of the control
volume conservation laws and various finite difference
formulations and comparisons of the performance of these
schemes on three test problems: Ni's bump in a channel, a
supersonic nozzle, and flow in a supercritical compressor
cascade.

ABSTRACT: (U) The query facility for their universal relation database system is now working. The fundamental paper unifying ideas on what a UR system can and should be has been published. A paper surveying developments in the field of universal relation systems was invited for the triennial IFIP Congress and was delivered in September. Some initial results on logical theories applied to the problem of updating views have been obtained. There have been a number of developments concerning inference of inclusion dependencies and on the complexity of deciding certain properties of data base schemes. Some interesting results on the difficulty of obtaining hash functions that work well for particular sets of data have been obtained and won an award. (Author)

ABSTRACT: (U) Parametric low-speed wind tunnel testing of several low aspect ratio half-span wings featuring outboard-blowing wing-tip jets has been accomplished. This effort was performed to extend the existing information base regarding lift augmentation of low aspect ratio wings to encompass tapered wings suitable for application to high-performance fighter aircraft. At an angle of attack typical for fighter aircraft takeoff, operation of the wing-tip jets was found to augment the lift coefficient of aspect ratio two wings by 25% to 35%, depending upon the value of the jet momentum coefficient and the wing taper ratio. At low angles of attack, the wing lift coefficients were augmented by as much as 120%, but the amount of lift augmentation decreased in inverse proportion to wing angle of attack. The worth of blowing outboard from the wing tips of fighter aircraft as a means of enhancing STOL performance was assessed. Diverting 70% of the engine bypass airflow to the wing tips reduced predicted takeoff and landing distances by 15%. Differential left-wing-tip-to-right-wing-tip modulation of the jet momentum can immediately produce up to 15,000 ft-lbs of additional roll control torque during low-speed landing approaches. UNCLASSIFIED REPORT

ABSTRACT: (U) This interim report describes the work performed during the first half of Phase II on the Two Step Holographic Fringe Linearization Interferometry Study. The FLI process consists of deflecting the object beam between holographic exposures to create linear fringes and spatial filtering of the image reconstructed from the hologram about the linear fringe carrier frequency. This filtering is meant to discriminate between subsurface defects and random fringe noise. During this phase a loading limitation for the FLI process (of one quarter wave/linear fringe period for the out-of-plane deformations) was demonstrated. To circumvent this limitation two modifications to the FLI process were investigated: Four-Exposure FLI - a Moire technique and Laser Pulse separation control with dynamic loading. With the former method linear fringes have been recovered from the random noise in a simulated laboratory experiment. Experiments to demonstrate the fringe shifts at defect locations with differential loading are still in progress. Preliminary experiments performed on the NADC holographic system indicate that it should be adequate, albeit cumbersome, to demonstrate the Laser Pulse Control Method. The finite element analysis is predicting the experimental fringe patterns obtained with

SUPPLEMENTARY NOTE: Prepared in cooperation with Arizona
Univ., Tucson. Optical Sciences Center.

ABSTRACT: (U) The Topical Meeting on Signal Recovery and
Synthesis with Incomplete Information and Partial
Constraints was held in Lake Tahoe, Nevada on January 12-
14, 1983. The meeting was open to all interested
scientists and engineers and was interdisciplinary in
scope. The program consisted of both invited fields and
contributed papers. The two and one-half day meeting
dealt with such diverse as image processing,
crystallography, astronomy, geophysical signal processing,
electron microscopy, optical information processing, and
remote sensing having encountered the problem of image
formation with missing information or unknown (or only
partially known) measurement system parameters. Specific
examples include phase retrieval from intensity
measurements, tomographic reconstruction with missing
projections, blind deconvolution, and multidimensional
spectral extrapolation and interpolation. A related set
of problems occurs in multidimensional signal processing
when system constraints are only partially specified.
Examples include computer holography and pupil synthesis
for incoherent optical processing. A common mathematical
structure is shared by all these application areas. The
purpose of this meeting was to bring together specialists
with interests in these diverse areas and to stimulate
interchange of ideas. (Author)

ABSTRACT: (U) This report describes the preparation of
an imagery data base containing 250 transparencies,
consisting of 25 degraded versions of each of 10
digitized images. The 25 degraded versions consist of 5
blur levels combined with 5 noise levels. Each image is
86 mm square and represents 4096 x 4096 8-bit pixels.
These images have corresponding ground truth, and the
blur and noise levels are verified and quantitatively
known. Subsequent stages of the research program will use
these images in experiments to compare image quality with
measured photointerpreter performance. An overview of the
research program is also provided. (Author)

ABSTRACT: (U) The Principal Investigator and the Co-Investigator attended four conferences giving papers at two of them. The Principal Investigator organized a Conference on Stochastic Failure Models, Replacement and Maintenance Policies, Accelerated Life Testing. He continued his research on shock models, wear processes, replacement and maintenance policies; revised the paper Life Distribution Properties of Devices Subject to a Levy Wear Process, wrote the paper Pure Jump Damage Processes. He also wrote Conservative and Dissipative Parts of Non-Measure Preserving Weighted Composition Operators. The Co-Investigator presented a paper on Approximate Optimal Replacement Policies and Their Stability.

ABSTRACT: (U) Volumes II and III together give an overview of the state of the art in computing complex turbulent flows in 1981 using the data base established for this purpose in Volume I. The materials are intended to be complete in the sense of providing all elements necessary for understanding the state of the art. Thus, Volumes II and III include: (1) Taxonomies that organize the flows, methods of modeling, numerics; (2) Comments by non-computers (the reporters) on results for each class of flows; (3) Discussions carried through to closure; and carefully edited (see Discussion Procedures in Volume I); (4) Samples of recent high-level research computations that are currently beginning to provide information of aid to turbulence modelers; (5) An overall evaluation of the state of the art; (6) An opinion on the question of universality of turbulence models; (7) All computer output compared with data, case by case; and (8) Comments by the computer groups on experience and problems.

ABSTRACT: (U) The Conference includes two meetings. The first, had the goal of establishing a data base of test cases for comparison with computations. This volume contains a record of the proceedings of the 1980 meeting and a display of the test cases used in the 1981 meeting for comparison with computations. The main sections of the volume include: (1) Pictorial summary charts providing a compact picture of the nature of the test cases. (2) Three position papers covering: (a) Data needs for computational fluid dynamics; (b) Some improvements to the theory of uncertainty analysis and the use of that theory for the present Conference; and (c) Description of Data Library. (3) Description of test cases including: Specifications for computations; and Output plots for the test cases. (4) Reports of ad-hoc committees on topics of general interest; and (5) Index to Flow Cases.

ABSTRACT: (U) This past year the proposed auditory-visual perceptuomotor paradigm was designed and implemented, and 12 twenty-one channel pilot recordings were conducted. The objective was to compare spatiotemporal brain-potential patterns associated with: (1) the preparation to receive auditory or visual numeric stimuli, and (2) the processing of auditory and visual numeric stimuli. A bimodal paradigm sufficiently controlled for the application of a 49 channel Neurocognitive Pattern (NCP) Analysis has been finalized and participant screening sessions have begun. Sections III and IV of this Interim Progress Report are comprised of published (Science, 220:97-99, 1983) and in preparation papers describing our recent visuospatial move/no-move study. The results of further signal processing studies on that data are described in Sections V and VI.

ABSTRACT: (U) This report summarizes the first year of research on a project to produce formalisms, suitable for manipulation by computer, for the representation of specific concepts that are important for natural-language semantics, and to give an independent account of the meaning of such representations using the tools of formal logic. The major technical achievement of this effort has been the development of a logic which characterizes systems which represent and reason with information about their own beliefs. Other problems worked on include the development of semantic representations for comparative constructions in English and the analysis of deductive methods for commonsense reasoning. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Kinetic and mechanistic investigations of the effects of oxygen pressure on liquid phase autoxidation reactions in model lubricants at elevated temperatures were carried out with n-hexadecane at 160 to 190 C and at oxygen pressures from 4 to 120 kPa. Results of these investigations showed that intramolecular alpha, gamma and alpha, delta hydrogen abstraction reactions of peroxy radicals are highly reversible and that the intermediate hydroperoxyalkyl radicals formed from these abstractions, besides addition of oxygen and reverse intramolecular hydrogen abstraction (isomerization) reactions, undergo cyclization reactions leading to formation of cyclic ether products. A general reaction scheme for autoxidation of any system containing alkyl chains with carbon number greater than four is proposed. Absolute rate constants for formation, isomerization, and cyclization of hydroperoxyalkyl radicals have been determined for the first time for liquid-phase autoxidation and the corresponding Arrhenius parameters have been derived. Their values are in general agreement with those previously determined or estimated in gas phase combustion studies. Results of kinetic analysis of cleavage product formation are consistent with two modes of their formation in the entire range of oxygen pressures studied. The first mode involves decomposition

ABSTRACT: (U) The research described in this report was directed towards a continued examination of visual cues used by pilots to maintain altitude in low level flight simulation. The first study investigated the use of a psychophysical technique to provide a quick, low-cost evaluation of altitude cues provided by five visual display system conditions in which terrain features were varied in detail, density, and vertical development. Both pilot and non-pilot observers were employed. A second study examined three visual display environments (i.e., a valley floor, a valley floor with walls, and a valley floor with walls and inverted pyramids) using different display modes (i.e., slides, static video, and dynamic video). Differences between pilot and non-pilot subjects were obtained for the accuracy of altitude estimation.

UNCLASSIFIED REPORT

ABSTRACT: (U) Multi-chamber, lumped parameter models of the pulmonary and circulatory systems have been developed which incorporate effects of whole-body accelerations (WBA) for any body orientation and a variety of breathing maneuvers. The pulmonary model has been used in an extensive study of effects of sustained WBA on pulmonary mechanics and ventilation. This study investigated the effectiveness of altering seat back angle to increase G-tolerance. The development and testing of the separate pulmonary and circulatory models has been reported in previous reports, as well as the above described WBA study. This final report describes latest efforts to incorporate feedback and control mechanisms in the circulatory model to simulate the baroreceptor and chemoreceptor actions regulating blood flow and blood pressure in the human body. This work is not yet complete. Also described is a partially completed study using the pulmonary model to test and implement a non-invasive technique for diagnosing ventilation distribution dysfunctions. (Author)

UNCLASSIFIED REPORT

ABSTRACT (U) Conflicts arising in distributed systems, as in contentions for shared resources, are resolved either by a central process or by resorting to probabilistic decision making by individual processes or by assigning a static global priority to each process. All known non-probabilistic solutions to the conflict resolution problem are asymmetric in the sense that they distinguish between processes by ordering process ids of by having some processes carry out special functions. We propose an efficient, fair, symmetric solution for this problem. Asymmetry is present initially by judicious placement of shared resources and asymmetry is preserved in a fair manner by our solutions. To provide a concrete framework for our discussion of conflict resolution we couch our discussion in terms of a generalization of the classical dining philosopher's problem.

UNCLASSIFIED REPORT

ABSTRACT: (U) An experimental and theoretical study of three-dimensional boundary layers on bodies of revolution at incidence was conducted during the period May 1980-July 1983. This final report summarizes the technical accomplishments. Reference is made to previous reports and papers resulting from the study and some recent experimental results on the boundary layer in the plane of symmetry and the vortex formation region are presented. One of the primary objectives of this study was to develop instrumentation for the measurement of the mean flow and the Reynolds stresses in three-dimensional turbulent boundary layers, and to use these to supplement the mean-flow measurements made earlier by Ramaprian, Patel and Choi on the combination body at an incidence of 15 degrees.

UNCLASSIFIED REPORT

ABSTRACT: (U) In the last several years, the investigators have developed a number of important, practical distributed algorithms for problems such as distributed simulation, termination and deadlock detection, computing networkwide functions in a distributed manner, etc. Interest in distributed systems has spurred publications of many distributed algorithms by other researchers. The major thrust in the past year has been directed towards developing unifying frameworks, i.e., paradigms - which consolidate the known results. They have developed a theory for detecting all system properties that are stable, i.e., properties that continue to hold once they begin to hold. Examples of stable properties are termination, deadlock, etc. The work subsumes a large body of literature on termination and deadlock detection. They have similarly developed a theory of conflict resolution and an algorithm based on this theory; this algorithm subsumes all known nonprobabilistic algorithms for mutual exclusion. In addition, they have continued work on models of distributed systems, their verification and performance analysis. (Author)

ABSTRACT: (U) The author's objective is the quantitative characterization of visual spatio-temporal channeling of information. The immediate approach of this study is to measure the detectability of a visual test stimulus which is a moving sinusoidal grating pattern, in the presence of a masking visual stimulus, which can be represented in spatio-temporal frequency space as band-limited two-dimensional dynamic visual noise. He has performed coherent masking studies in which the mask is a high-contrast traveling wave grating and have discovered that the masking function is very asymmetrical in spatial frequency when the mask and test gratings are matched in velocity. It was also discovered that band limited two-dimensional visual noise can be simulated by discrete (punctate) spectral components lying within the desired band and that as few as six components can give a representation indistinguishable from continuous-spectrum noise. To perform these band-limited visual noise studies the author created a unique computer-controlled system for image generation.

ABSTRACT: (U) Estimation of parametric families for small data sets where a significant portion of the data lay below fixed instrument detection thresholds was investigated. Thus the number of data points was random (an example of Type I censoring). Both analytic and simulation procedures were utilized. In particular, maximum likelihood techniques, order statistic techniques, truncation techniques, fill-in with constants, and fill-in with expected values of the missing points were investigated. For exponential data, truncation seemed most appropriate while for normal and log-normal data, fill-in with expected values (modified to correct for conditioning on the number of data points) was best. The criteria for selection was the total square error. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The chemical (macromolecular) structure and biological function of the eukaryotic cell specific nuclear polymer, polyadenosine diphosphoribose has been investigated in specific cell nuclei isolated from animals (rats) and from human fibroblast cultures. This polymer is formed enzymatically from NAD in eukaryotic nuclei. The polymer was identified for the first time, as a unique nucleic acid structure which can form helix-helix type non-covalent association between long chain polymers that are on one end covalently bound to non histone proteins, comprising a supramolecular DNA structure associated network system. The influence of differentiation determined by assays in different cell types within one organ and effects of developmental hormones in animals on polyadenosine diphosphoribosylation and the role of the polymer in cell transformation in cell cultures has been studied by focusing on the quantitative and qualitative changes of non histone protein-polyadenosine diphosphoribose adducts in chromatin under controlled experimental conditions. A positive correlation was found between changes (inhibition) in rates of polyadenosine diphosphoribosylation and cellular hypertrophy of cells incapable of DNA synthesis indicating a physiologic control function of the polymer-protein network system in DNA template activity in these cells.

SUPPLEMENTARY NOTE: Prepared in cooperation with Case Western Reserve Univ., Cleveland, OH.

SUPPLEMENTARY NOTE: Prepared in cooperation with Georgia Inst. of Tech., Atlanta. School of Information and Computer Science and Toronto Univ. (Ontario). Computer Systems Research Group.

ABSTRACT: (U) Necessary and sufficient conditions are given for the almost sure convergence of a quadratic form where $(M \text{ sub } j)$ is a sequence of i.i.d. p-stable random variables. A connection is established between the convergence of the quadratic form and a radonifying property of the infinite matrix operator $(f \text{ sub } kj)$. (Author)

ABSTRACT: (U) Two notions of dependency satisfaction, consistency and completeness, are introduced. Consistency is the natural generalization of weak-instance satisfaction and seems appropriate when only equality-generating dependencies are given, but disagrees with the standard notion in the presence of tuple-generating dependencies. Completeness is based on the intuitive semantics of tuple-generating dependencies but differs from the standard notion for equality-generating dependencies. It is argued that neither approach is the correct one, but rather that they correspond to different policies on constraint enforcement, and each one is appropriate in different circumstances. Consistency and completeness of a state are characterized in terms of the tableau associated with the state and in terms of logical properties of a set of first-order sentences associated with the state. A close relation between the problems of testing for consistency and completeness and of testing implication of dependencies is established, leading to lower and upper bounds for the complexity of consistency

UNCLASSIFIED REPORT

ABSTRACT: (U) Given a fixed set S of n keys, we would like to store them so that queries of the form 'Does the point X belong to the set S ?' can be answered quickly. A commonly employed scheme to solve this problem uses a table to store the keys, and a special purpose program depending on S which probes the table. We analyze the tradeoff between the maximum number of probes allowable to answer a query, and the information-theoretic complexity of the program to do so. Perfect hashing (where the query must be answered in one probe) has a program complexity of n times the log e to the base e ($1+O(1)$) bits, and this lower bound can be achieved. Under a model combining perfect hashing and binary search methods, it is shown that for k probes to the table $nk/2$ to the $k+1$ power ($1+O(1)$) bits are necessary and sufficient to describe a table searching algorithm. This model gives some information-theoretic bounds on the complexity of searching an external memory. Finally, we prove some lower bounds on the worst case performance of hash functions described by bounded Boolean circuits, and worst case performance of universal classes of hash functions.

ABSTRACT: (U) It is shown, that in many cases globally defined, bounded solutions of evolution equations are as smooth (in time) as the corresponding operator, even if a general solution of the initial value problem is much less smooth; i.e., initial values for bounded solutions are selected in such a way that optimal smoothness is attained. In particular, solutions which bifurcate from certain steady states such as periodic orbits, almost-periodic orbits and also homo- and heteroclinic orbits have this property. As examples a neutral functional differential equation, a slightly damped non-linear wave equation, and a heat equation are considered. In the latter case the space variable is included into the discussion of smoothness. Finally, generalized Hopf bifurcation in infinite dimensions is considered. Here this document discusses smoothness of the bifurcation function and generalize known results on the order of a focus. (Author)

ABSTRACT: (U) In order to more fully understand the physiological and psychological significance of event-related potentials, cortical and subcortical recordings are being obtained from monkeys performing in operant-conditioning tasks. Six animals were trained on initial phases of the cued reaction-time task at SRI International and were subsequently implanted with electrodes capable of recording transient and sustained evoked potentials and massed-unit activity. Two monkeys were trained on initial phases of an 'oddball' task at Stanford University, and electrodes are being prepared so that the subcortical generators of the P300 wave can be assessed in these animals. An LSI-11/23 computer system was installed at SRI to implement the cued reaction-time task and to collect event-related potentials. Preliminary recordings of slow potentials and massed-unit activity were collected from the lateral geniculate nucleus of one cat to evaluate the performance of modified amplifiers, and transient (P300) and sustained (contingent negative variation) evoked potentials were recorded from the scalps of human subjects to confirm appropriate performance of the laboratory system. UNCLASSIFIED REPORT

ABSTRACT: (U) The assumptions and criteria used in existing analyses in determining the regions and transition lines of pseudo-stationary oblique-shock-wave reflections were re-examined in order to improve the agreement between experiments and computed data for regular (RR), single-Mach (SMR), complex-Mach (CMR) and double-Mach reflection (DMR). It is shown that the relaxation lengths for vibration and dissociation determine whether frozen or equilibrium gas transition lines are applicable. The available experimental data in N₂, CO₂ and air, which are based on the criterion delta, (consistent with relaxation lengths) of the angle delta, between the incident and reflected shock wave, do not conclusively support the frozen or equilibrium gas calculations for N₂ and air. It does support CO₂ as an equilibrium gas contrary to a previous conclusion of agreement with gamma = 1.29. A new additional and necessary criterion for the transition from single to complex Mach reflection improves the agreement between analysis and experiment and is consistent with the requirements of the relaxation length and the angle delta. However, it now appears that a more accurate criterion is required for the boundary line between CMR and DMR. More detailed examination of the boundary-layer-displacement

ABSTRACT: (U) Research results are summarized for system parameter identification utilizing time limited input-output data. The results stem from two fundamentally different approaches, one of which stems from a projected integral equation error formulation and the other from a modulating function formulation for converting differential equations to functional equations. Applications include the parameter identification of differential-delay systems, delay estimation in received signals, identification of time varying systems, and estimating target acceleration in pursuit-evasion problems. ABSTRACT: (U) This paper describes the development of a multi-element hot-wire anemometry system designed to measure a wide variety of fluctuating velocity and temperature quantities in non-isothermal boundary layer flows. Descriptions of the design and evaluation of the multi-element probes and the analog-digital data recording and analysis system are included. Special features of this system were: (1) that the hot-wire probes employed sensors of reasonably practical size (2.5 microns dia.); and (2) that only standard, commercially available constant-temperature anemometers were utilized. Sample data, including Reynolds stress and turbulent Prandtl number distributions, demonstrate that boundary layer turbulence statistics were measured accurately with this system. (Author)

ABSTRACT: (U) The objective of this project was to develop and validate a criterion with which the Air Force could reliably evaluate the compatibility of an individual's physical capacity with the physical demands of the various Air Force Specialty Codes (AFSCs). The benefits derived by the Air Force from this capability are a reduction in early discharges due to the inability of the individual to physically qualify for an AFSC after enlistment; a corresponding decrease in training costs, both initial and cross-training, due to a lower probability of an individual's eventual failure in the AFSC; a reduction in injury related costs due to a fewer number of individuals performing physical work at levels near or exceeding their maximum safe capability to work; and a reduction in operating costs by improving the work force capacity relevant to the physical demands of the task.

UNCLASSIFIED REPORT

ABSTRACT: (U) Proposed future space-based beam weapons systems will most probably require an intense neutral particle beam for effective operation across geomagnetic field lines. Such neutral beams can most efficiently be obtained by stripping excess electrons from negative ion beams. The objective of this work is to study the process of dissociative attachment of electrons. Specifically, to measure the cross sections for polar dissociation and dissociative attachment for production of H(-). It is suspected that these dissociative attachment cross sections for the production of H(-) from alkali hydrides are large. The insight gained from this study will be extremely helpful in the fabrication of high current density H(-) beam sources for use in the production of intense neutral hydrogen beams. A selection of alkali hydride molecules will be investigated in order to determine the largest cross sections for the production of H(-) by electron impact. The angular distribution of the H(-) ions will be measured. An optimal vapor pressure for the efficient production of H(-) will be found. The feasibility of extending the proposed research to the deuterium bearing molecule will be determined.

UNCLASSIFIED REPORT

ABSTRACT: (U) The author spent one half of the Spring 1983 semester at the Institute for Mathematics and its Applications. During that time he interacted with colleagues, engaged in research, and gave two public lectures at the Institute: Chaos in Phase Transitions, and Dynamics of Phase Transitions. The main thrust of his research was in two areas, specifically: Deterministic chaos in materials exhibiting phase transitions, and Admissibility criteria for weak solutions of the non-hyperbolic conservation laws which describe dynamic phase transitions.

ABSTRACT: (U) During this period the principal investigator has considered the effect of the artificial far field boundary on a finite different approximation of the Navier-Stokes equations for a compressible fluid considered for two dimensional boundary conditions for the far-field boundary can results in some of the following phenomena: (1) reflecting boundary conditions, in which the disturbances in the physical variables represented by the difference between the steady state flow and the initial conditions are not allowed to exit through the far-field boundary but instead continue echoing up and down the grid; (2) under-specified boundary conditions, in which the converged steady state solution may depend on the initial conditions; and (3) over-specified boundary conditions in which large errors are introduced before convergence takes place. The following conclusions may be drawn from the numerical experiments conducted as a part of the research effort: There are four distinct artificial nonreflecting boundaries containing free-stream information, these being the inflow, outflow, top-sidewall and bottom-sidewall. Each of these boundaries must be treated differentially, or errors are introduced into the system.

ABSTRACT: (U) The author review various aspects of the control theory of hyperbolic systems, including controllability, stabilization, control canonical form theory, etc. To allow a unified and not excessively technical treatment, attention is restricted to the case of a single space variable; the multi-dimensional case is treated in another work. The paper concludes with a short discussion of the newly developed procedure of canonical augmentation. (Author)

ABSTRACT: (U) An inverse method was developed for treating gas-particle supersonic flow past axisymmetric blunt bodies. This method is based on two transformations (von Mises and an additional one), which are convenient for determining the shock-layer flow fields and the body shapes. In using the present method, the pure gas flow fields around spheres were first solved numerically for the freestream Mach numbers = 10, 6, 4, 3, 2 and 1.5. These were found to be in very good agreement with the available results of Van Dyke and Gordon. Then the gas-solid-particle flow in the shock layer around blunt bodies (nearly spheres) were solved for the freestream Mach numbers = 10 and 1.5, with freestream loading ratios = 0, 0.2, 0.5 and 1.0 and particle diameters 1, 2, 5 and 10 micrometers respectively.

UNCLASSIFIED REPORT

ABSTRACT: (U) Modeling of linear stochastic systems leads to the stochastic realization problem. In this project the author develops a comprehensive theory of stochastic realization. Such a theory should be the center-piece of stochastic systems theory. First he studies the problem from a coordinate-dependent point of view. Secondly, he develops a geometric theory of Markovian representation, which also accommodates infinite-dimensional systems. In this framework a unified theory of smoothing is provided, the basic idea being to embed the given stochastic system in a class of similar systems all having the same output process and the same Kalman-Bucy filter. This approach provides stochastic interpretations of many important smoothing procedures. The factorizations of the matrix Riccati equation underlying fast (non-Riccati) algorithms are analyzed in the context of Hamiltonian systems, and certain aspects of the algebraic Riccati equation are studied, as is the concept of invariant directions of the matrix Riccati equation. A unified approach to the partial realization problem is taken, incorporating ideas from numerical linear algebra. Also studied are questions of stability of partial realizations. Finally, a statistical approach to stochastic optimization is presented, and convergence results for algorithms based on stationary data are obtained.

ABSTRACT: (U) This document reports progress on Simply
Instrumentable and Optimal Digitization of Analog
Information Sources. New techniques for encoding sources
with and without memory are described in Section 1 and
the papers, presentations, and theses supported by the
research are listed in Section 2. Three new optimal
coding methods, generalizing previous ones, have been
discovered for stationary Gaussian sources and the
squared-error distortion measure. These methods, which
store codewords on trees and trellises and utilize
systematic search algorithms, are being applied to actual
speech and image data. Also, the code storage
requirements are not large, as this research has shown
that small code letter alphabets give nearly optimal
results. (Authors)

ABSTRACT: (U) During the 1982/83 first year performance-
period under this Grant, research investigations have
been carried out leading to significant results, of both
theoretical and practical importance. A large multitude
of computer communication network architectures, models
and control schemes have been developed, analyzed and
evaluated. In particular, results have been obtained in
the following areas: priority-based Time Division
Multiple Access schemes; dynamic random-access procedures,
with applications to local area networks and to local
distribution and packet-radio networks; hybrid multiple-
access schemes; polling, adaptive polling and probing
access-control techniques; buffer capacity constrained
multi-access systems; network topological analysis; local
area network topological analysis; local area network
protocols; integrated packet and circuit networks;
integrated routing and flow control.

ABSTRACT: (U) During the period of this grant the investigators addressed nonlinear resonance and interactions involving systems of nonlinear ordinary differential equations with slowly varying coefficients. More specifically, they investigated passage through resonance, sustained resonance as in roll resonance, particle accelerators or free electron lasers, global adiabatic invariants and weakly nonlinear wave interactions. Approaches used included matching asymptotic expansions, multiple scale expansions, higher order averaging, the Melnikov method and near identity canonical transformations to obtain global adiabatic invariants. ABSTRACT: (U) The structure of time-scales in systems of the form $\dot{x} = A(\epsilon)x$ is related to the invariant factors of $A(\epsilon)$ when this matrix is over the ring of functions analytic at 0. This relationship motivates the study of invariant factor assignment in the matrix $A(\epsilon) + B(\epsilon)K(\epsilon)$ by choice of $K(\epsilon)$. Results on this problem have implications for assignment of timescales by state feedback in systems of the form $\dot{x} = A(\epsilon)x + B(\epsilon)u$. Work in this direction is presented. (Author)

ABSTRACT: (U) The goal of this Multi-Investigator Research Program (MIRP) is to achieve an understanding of the science of ultrastructure processing. Ultrastructure processing refers to the manipulation and control of surfaces and interfaces to attain a new generation of high performance materials with predictable properties and environmental insensitivity. Problem areas that may benefit from the use of ultrastructure processing include: behavior of particulate solids, adhesion of fillers and reinforcements in composites, corrosion of glasses and glass-ceramics, fatigue of brittle materials, grain boundary attack of ceramics, effects of energetic particle beams, lifetime of non-oxide ceramics, electronic behavior of high band gap semiconductors, multiphase electronic components.

ABSTRACT: (U) Given a universal relation scheme,
presented as a set of attributes and a set of
dependencies, it may be advantageous to decompose it into
a collection of schemes, each with its own sets of
attributes and dependencies, which has some desired
properties. A basic requirement for such a decomposition
to be useful is that the corresponding decomposition map
on universal relations be injective. A central problem in
database theory is to find the reconstruction map, i.e.,
the inverse map of an injective decomposition map. We
prove here that when the decomposition, viewed as a
hypergraph, is acyclic and the given dependencies are
full implicational dependencies, then the reconstruction
map is the natural join. Based on this, we show that
there is a polynomial time algorithm to test for
injectiveness of decompositions.

ABSTRACT: (U) This research has been concerned with films that are metastable compounds or multilayered composites which are quenched from the vapor phase. They have been stabilized by a number of methods which aid in the quench or by growing upon especially prepared surfaces upon which epitaxial growth can take place. The occurrence of superconductivity in the metastable films has been investigated. Newly developed methods of heat capacity and tunneling techniques have been used to study the superconducting interactions and to provide the increased understanding of the mechanisms of superconductivity necessary to reach higher transition temperatures.

ABSTRACT: (U) The authors describe techniques for estimating temporally and spatially dependent parameters (including coefficients) that appear in general transport models. Convergence properties of the resulting algorithms are given and sample computational findings with test examples are presented. The authors conclude with a summary of their use of the methods analyzing experiments on the movements of marked flea beetles in cultivated arrays of the cole crop, collards (Brassica oleraceae). (Author)

ABSTRACT: (U) The authors present convergence arguments for algorithms developed to estimate spatially and/or time dependent coefficients and boundary parameters in general transport (diffusion, advection, sink/source) models in a bounded domain Omega C R sub 2. A brief summary of numerical results obtained using the algorithms is given. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This report is comprised of two parts. In Part I a predictive model for an apparent flame length in a co-axial jet diffusion flame combustor is described. According to this model a diffusion flame is considered as thin cylindrical reactive zone composed of chemically active and dead regions. Fuel consumption by surface oxidation is assumed. Mass transport of oxygen to the reactive surface is considered to control the overall combustion process. Overall mass transfer coefficient, evaluated from an empirically developed correlation, is employed to predict total flame length. Comparison of the experimental and predicted data on total flame length shows a reasonable agreement within sixteen percent over the investigated air and fuel flow rate ranges of 1-2kg/s and 5-11kg/hr, respectively. In Part II a scheme to predict an apparent flame length is described for the circumstances when a recirculation region established immediately downstream of a center-body in a co-axial jet combustor is penetrated by a central fuel jet. A turbulent jet flow theory has been coupled with the theory given in Part I of the report.

DESCRIPTORS: (U) *Flames, *Combustion, *Jet flow, Length, Diffusion, Turbulent flow, Kinetics, Mass transfer, Mathematical models, Fuel consumption

ABSTRACT: (U) The research performed under this grant centers on the concept of a network computer. By this the authors mean a network of computers (no shared memory) which can be programmed as if it were a single virtual machine using a high level distributed language. Work during this past year can be divided into three areas: Distributed Algorithms; Distributed Languages; and An Implementation of Multicasting on a Network Computer. This report summarizes progress achieved during the past year. (Author)

ABSTRACT: (U) The research program was focused on investigating new methods of analysis, synthesis, and optimization of control systems, particularly those which contain disturbance inputs, uncertain parameters, and other modeling uncertainties. The general objective was to develop new methods to improve the performance of control systems by counteracting the effects of these modeling uncertainties and disturbance inputs. The new methods can be classified into several general categories; multivariate feedback design in the frequency domain based on the comparison sensitivity matrix and robustness concepts, adaptive observers and adaptive control, multiple time-scale and singular perturbations, chained aggregation methods, and incentive controllers for hierarchical systems. ABSTRACT: (U) Critical examination of experimental,
analytical and numerical research on shear-flow
instabilities evolving into turbulence led to a
conceptual framework consistent with reliable
observations. Mechanically driven shear layers fall into
four classes: boundary layers, confined duct flows, free
shear layers, and flows in annuli between cylinders
driven by the rotation of the inner cylinder. These
classes correspond to distinct, initially rather
homogeneous vorticity distributions. Each instability
restructures these distributions; it dehomogenizes them
spatially, while the very slow viscous effects smooth the
largest gradients. The restructuring continues even after
the shear layers become turbulent.

ABSTRACT: (U) This volume is the proceedings of a
symposium hosted by the John B. Pierce Foundation and
held at Yale University, New Haven, Connecticut, on
October 26-27, 1981. The goal of the symposium was to
bring together engineers, physical scientists,
physiologists, and psychologists to discuss how
nonionizing electromagnetic radiation deposits
thermalizing energy in biological tissues and the means
by which this energy may be detected and effectively
managed by the conscious organism.
